Seed Micromorphology of Neotropical Begonias

A. de Lange

and

F. Bouman
Emphasis upon publication as a means of "diffusing knowledge" was expressed by the first Secretary of the Smithsonian. In his formal plan for the institution, Joseph Henry outlined a program that included the following statement: "It is proposed to publish a series of reports, giving an account of the new discoveries in science, and of the changes made from year to year in all branches of knowledge." This theme of basic research has been adhered to through the years by thousands of titles issued in series publications under the Smithsonian imprint, commencing with *Smithsonian Contributions to Knowledge* in 1848 and continuing with the following active series:

*Smithsonian Contributions to Anthropology*
*Smithsonian Contributions to Botany*
*Smithsonian Contributions to the Earth Sciences*
*Smithsonian Contributions to the Marine Sciences*
*Smithsonian Contributions to Paleobiology*
*Smithsonian Contributions to Zoology*
*Smithsonian Folklife Studies*
*Smithsonian Studies in Air and Space*
*Smithsonian Studies in History and Technology*

In these series, the Institution publishes small papers and full-scale monographs that report the research and collections of its various museums and bureaux or of professional colleagues in the world of science and scholarship. The publications are distributed by mailing lists to libraries, universities, and similar institutions throughout the world.

Papers or monographs submitted for series publication are received by the Smithsonian Institution Press, subject to its own review for format and style, only through departments of the various Smithsonian museums or bureaux, where the manuscripts are given substantive review. Press requirements for manuscript and art preparation are outlined on the inside back cover.

1999
ABSTRACT

Lange, A. de, and F. Bouman. Seed Micromorphology of Neotropical Begonias. Smithsonian Contributions to Botany, number 90, 49 pages, 1 figure, 21 plates, 1999. — The seeds of about 235 Neotropical Begonia species, representing almost all recognized American Begonia sections, were studied using scanning electron microscopy. The seeds show an appreciable diversity in size, shape, and micromorphology, which is helpful in the delimitation of sections and sometimes also of species. Mean seed length varies from 235 μm in Begonia filipes to 1450 μm in B. fruticosa; most seeds have a length between 300 μm and 600 μm. The shape of the seeds varies from almost globular to narrowly elliptic, and the length to width ratio ranges from 1.2 in B. hexandra to 8.1 in B. fruticosa. Further differences exist in the shape of the testal cells, the undulation of the anticlinal walls, the bulging of the outer periclinal walls, and the pattern and roughness of the cuticle.

Five of the 15 mainly Brazilian, five of the 12 Andean and Guianan, and one of the eight middle American sections have a seed structure that is characteristic at the sectional level. All these sections have a relatively restricted geographical distribution, and they may differ in growth form or habitat. Most species of the other sections, including the larger and more widely distributed sections Begonia, Giroudia, and Knesebeckia, have seeds conforming to the ordinary seed type.

In a number of the sections, the structural differences of the seeds are nicely correlated with differences in growth form and/or in means of dispersal. In contrast to the African begonias, the great majority of the Neotropical begonias have anemoballistic dispersal. Seeds may be adapted to wind dispersal by extended micropylar and/or chalazal ends with inflated, air-filled cells, such as in the Brazilian sections Solananthera, Trendelenburgia, and Enita; and in the Andean section Rossmannia, or by a more pronounced surface with deep, collapsed testal cells, such as in sections Gobenia and Scheidweileria. Zooballistic dispersal by passing animals is supposed to be present in section Casparyia. The seeds of sections Casparyia and Trachelocarpus have very pronounced cuticular patterns and may be secondarily dispersed by rain wash or by adhering to animals.

No distinct indications for an intercontinental relationship between Neotropical, African, and Asiatic sections could be established.

OFFICIAL PUBLICATION DATE is handstamped in a limited number of initial copies and is recorded in the Institution's annual report, Annals of the Smithsonian Institution. SERIES COVER DESIGN: Leaf clearing from the katsura tree Cercidiphyllum japonicum Siebold and Zuccarini.

Seed Micromorphology of Neotropical Begonias

A. de Lange
and F. Bouman

Introduction

The genus *Begonia* L. represents one of the larger genera of flowering plants and has a complicated taxonomic history. Generic concepts in the family Begoniaceae have changed much; about 50 genus names have been put into synonymy with *Begonia*. According to current opinions, the family comprises only the genera *Begonia*, *Hillebrandia*, and *Symbeugonia*, although *Symbeugonia* was classed under *Begonia* by Mabberley (1989). *Hillebrandia sandwicensis* Oliver, of the monotypic genus *Hillebrandia*, is endemic to Hawaii.

According to Smith et al. (1986) and Golding (1992), *Begonia* comprises almost 1400 species arranged into 78 sections (Baranov and Barkley, 1974), some of which are dubious or under discussion. Each section is restricted to a single continent except sections *Begonia* and *Knesebeckia*, which have an American-Asian distribution.

The seeds of Begoniaceae are characterized at the family level by the presence of a transverse ring of so-called collar cells. These cells are usually elongated and border the micropylar-hilar part of the seed. During germination, this part separates along preformed rupture lines and is lifted off like a seed lid or operculum (Figure 1), and the walls between the collar cells split to clear the way for the emerging seedling (Bouman and de Lange, 1983). The seeds of begonias show an appreciable diversity in size, shape, and micromorphology. The most common "ordinary" *Begonia* seeds mostly measure between 300 µm and 600 µm long. As far as is known, the extremes are found among the African begonias: the smallest seeds are recorded from *B. iucunda* Irmscher, with a mean seed length of 220 µm, and the largest are from *B. ebolowensis* Engler, with a mean length of 2240 µm (de Lange and Bouman, 1992).

The African begonias have received considerable attention by De Wilde and colleagues during the last 15 years (de Wilde, 1985, 1992). Using a multidisciplinary approach (including karyology, pollen morphology, stigma morphology (Panda and de Wilde, 1995), placentation, seed morphology, and leaf anatomy (Sosef, 1994)), sections have been revised and intersectional relations have become clearer. A comparative scanning-electron-microscopy (SEM) study proved seed micromorphology to be a very useful additional character set, especially at the sectional level (de Lange and Bouman, 1992). The African begonias showed a considerable diversity in seed size and

Reviewers: K. Burt-Uikey, Department of Biological Sciences, University of New Orleans, New Orleans, Louisiana; D.C. Wasshausen, Department of Botany, Smithsonian Institution, Washington, D.C.
structure. Moreover, differences in seed structure appeared to be distinctly related to the means of seed dispersal. In contrast to the general opinion that wind dispersal is the predominant means of dispersal in Begonia (van der Pijl, 1972), the seeds of the majority of the African Begonia species are dispersed by alternative ways. Animals may eat the fleshy, often colored fruits; seeds also may be dispersed by mud on the legs of passing animals or by rain wash (de Lange and Bouman, 1992).

The taxonomy of the Neotropical begonias is far from settled. During his long botanical career, Lyman B. Smith, in cooperation with Bernice G. Schubert and later Dieter C. Wasshausen, published a series of contributions to regional or national floras. Taxonomic revisions at the sectional level, however, unfortunately are lacking, with the exception of the study by Burt-Utley (1985) on the Central American and Mexican species of section Gireoudia. Because of the lack of a recent, updated revision of the Neotropical Begonia sections we have mainly followed the publication of Baranov and Barkley (1974) for sectional classifications and for the determination of their type species. It is important, however, to realize that their work was in large part based on published descriptions and did not involve critical examination of many species. A number of new sections described later have been added. For the sectional affiliation of species, we have used the publication of Barkley and Golding (1974) supplemented with data from later publications on newly described species.

In the Neotropics, about 600 Begonia species are recognized. According to Baranov and Barkley (1974), these are arranged in 47 sections; however, four of these sections, Auriformia, Irmscheria, Quadriperigonia, and Saueria, have since been eliminated due to synonymy. The monotypic section Dasystyles is of uncertain origin and is based on cultivated specimens. Twenty of the sections dealt with in the present paper have held generic status in the past (e.g., Casparya, Gireoudia, Huzia, Prizelia, Scheidweileria).

For convenience, we have arranged the sections discussed herein according to six areas of geographical distribution. Thirty-five sections have a restricted geographical distribution, with the species of 15 sections confined mainly to Brazil and some adjacent countries, 12 sections confined to the Andean and Guianan regions, and eight sections confined to the Central American, Mexican, and Caribbean regions. The species of seven sections have a wider distribution: two sections occur in both Brazilian and Andean regions, one section occurs in both Andean and Central American regions, and four sections have a more extended Neotropical distribution.

The possibility of a sectional classification within the genus Begonia has been questioned repeatedly. Smith and Schubert (1946) discussed the use of placental form as the basis for division into sections but in subsequent publications ignored sections altogether. In her description of the begonias of Madagascar, Keraudren-Aymonin (1983) also renounced classifying species into previously recognized sections. The studies on African begonias, however, clearly demonstrated the sensibleness and usefulness of a sectional division. Sosef (1994:11) made a strong plea to taxonomists always to denote the section to which any given species belongs.

Our study aims at a better insight into the diversity of seed structure of Neotropical begonias and the adaptive characters for dispersal. Moreover, it may provide arguments for sectional delimitation.

ACKNOWLEDGMENTS.—The authors are much indebted to J. Doorenbos (Department of Horticulture, Wageningen, the Netherlands), who sparked our enthusiasm for Neotropical begonias and who supplied us with a number of seed samples from his former collection of cultivated species. Moreover, he critically reviewed the manuscript and especially added valuable data to the descriptions and relationships of the sections. We thank the late Lyman B. Smith (National Museum of Natural History, Smithsonian Institution, Washington, D.C.) for his indications of taxonomic problems on sectional delimitation. Dieter Wasshausen (NMNH) is gratefully acknowledged for his interest and hospitality during the first author’s visit to the United States National Herbarium.

We thank J.J.F.E. de Wilde and M.S.M. Sosef of the Department of Plant Taxonomy, Wageningen Agricultural University, for their stimulating discussions on Begonia systematics. The directors and curators of herbaria cited in the text are gratefully acknowledged for providing facilities to study their collections or for loan of material.

M.G. Bouman and N. Devente assisted in the typing of the manuscript, F.D. Boesewinkel and J. Dahmen processed several thousands of SEM photographs, and W. Takkenberg provided technical assistance with SEM (Hugo de Vries-Laboratory, Amsterdam). The Netherlands Organization for Scientific Research financed the visit of the first author to the herbaria of Washington, D.C., and St. Louis, Missouri.

MATERIAL AND METHODS.—Most of the seed material was collected by visits to and/or by loan from the following herbaria: AAU, AMD, B, COL, CR, G, GENT, K, L, MO, P, PDA, PRE, RB, SP, U, US, and WAG. Moreover, seeds were received from the American Begonia Society Seed Fund (ABS), the former collection of cultivated begonias at the Department of Horticulture, Wageningen (WAG), and from the collections of L. Goldsmith (University of Vermont (VT)) and R. Ziesenhenne (Santa Barbara, California). Of the seeds received from Ziesenhenne, vouchers are present in his personal herbarium. No vouchers are available for the seeds obtained from ABS.

For the smaller sections, seeds of all available species were collected and studied. For the larger sections, seeds of a number of representative species were chosen. Mature seeds were sputter-coated with gold-palladium for 2 to 3 minutes and were observed using either a Cambridge Stereoscan MK 2a or an ISI DS-130. Dirty seeds were cleaned by soaking in water with a detergent and by subsequent ultrasonic vibration.

Seed size was determined from SEM measurements of usually six seeds. The seed width was measured at the widest apparent point. All mentioned mean sizes are arithmetically determined.
Description of Seeds of Neotropical Begonias

In the descriptions of Neotropical Begonia seeds, we emphasize those sections with a characteristic seed structure that sometimes can be related to special growth forms or to methods of seed dispersal. Sections with seeds conforming to the ordinary seed type are dealt with more briefly. Although variation in seed micromorphology between sections can provide taxonomic information, in view of the issue of correct identifications and the sometimes complicated nomenclature, detailed comparative studies are most valuable when done in close cooperation with taxonomists.

The results are presented according to the main geographical distributions of the sections for reason of surveyability and are not intended to suggest evolutionary relationships.

1. Sections Mainly Confined to Brazil and Some Adjacent Countries

Of the 15 Brazilian or mainly Brazilian sections, five (Enita, Scheidweilleria, Solananthera, Trachelocarpus, Trendelenburgia) share a unique seed structure that is characteristic at the sectional level. Seeds of the species within each of these sections can be distinctly discerned from those of all other sections. Of nine remaining sections, the seeds of all or most species have a more ordinary structure. No seeds were available from B. schlumbergerana Lemaire of the monotypic section Plurilobaria. This section is questionable because it is based on a dubious type species described from a cultivated specimen, probably related to section Ewaldia (Warburg, 1894).

1.1. Section Trachelocarpus A. DC.

PLATE 1a–c,e,f

This taxon was first described by Klotzsch as the genus Trachelanthus in 1855. C. Mueller (1857) changed the name to Trachelocarpus, and subsequently A. de Candolle (1859) reduced its status to sectional level. The section now comprises six species, restricted to Brazil. The taxonomically correct section type (Doorenbos et al., 1998) is Begonia depauperata Schott (= B. rhizocarpa Fischer ex A. DC.). Seeds were not available for B. angraensis Brade, B. fulvo-setulosa Brade, or B. velloziana Walp.

The species of the section are characterized by a rhizomatous habit and almost equal-sided lanceolate leaves. Moreover, the inflorescences are unisexual: the male ones are stalked cymes; the female ones are reduced to a single subsessile flower. The ovary and fruit have three narrow wings joining a beak-like elongation bearing tepals and styles with stigmas. All species are epiphytic, creeping herbs.

Type Species.—Begonia depauperata (Plate 1e).

Seed Structure: Seeds ellipsoid to narrowly ellipsoid, 750–830 μm in length, 305–330 μm in width, mean 800 μm x 320 μm, length:width ratio 2.5. Collar cells relatively short, 175–280 μm in length, mean 205 μm, number in seed circumference about 14. Ratio of collar-cell length to seed length 1:4.0. Other testa cells polygonal, arranged in rows of about 10 cells. Anticlinal walls straight to slightly curved. Testa cells shallow, with collapsed outer periclinal walls forming ridges parallel to anticlinal boundaries. Operculum obtuse, composed of many irregularly arranged small cells.

Seed Micromorphology: Anticlinal boundaries straight or sometimes sunken. Cuticle with net-like structure of upright or folded-over pleats. Cuticular striae usually occurring only locally, especially on anticlinals or in patches on smaller apical cells of operculum.

Specimen Examined: B. depauperata, BRAZIL: Campos Goer 140 (B).

Other Species Observed (Plate 1a–c,f)—Seed Structure and Micromorphology: Begonia herbacea Velloso and B. lanceolata Velloso (syn. B. attenuata A. DC.) have seed structures that resemble those of B. depauperata in general morphology and cuticular structure. Seeds of B. herbacea have a mean size of 850 μm x 370 μm. Seeds of B. herbacea var. ellipticifolia Irmscher are slightly longer, 855–935 μm (mean 910 μm x 370 μm), have a length:width ratio of 2.5, and the anticlinal boundaries of the collar and testa cells are much more distinctly sunken. The seeds of B. lanceolata have a mean size of 1030 μm x 410 μm.

Specimens Examined: B. herbacea var. ellipticifolia, BRAZIL: Ule 4240 (B). B. herbacea var. herbacea, BRAZIL: Loejesen s.n. (B); Lisedecceaeas s.n. (B). B. lanceolata, BRAZIL: L.B. Smith & Pereira 15343 (US).

1.2. Section Solananthera A. DC.

PLATE 1d,g,h

The section Solananthera was established by A. de Candolle in 1859. It contains three species restricted to Brazil. The species are epiphytic, climbing subshrubs. The section is characterized by the presence of porate anthers and two-divided placentas, the lobes of which cling to each other. The seeds of the three species have been described in detail (de Lange and Bouman, 1986).

Type Species.—Begonia solananthera A. DC. (Plate 1d).

Seed Structure: Seeds narrowly elliptic to narrowly obovate, mostly straight, sometimes J- or G-shaped. Mean seed size 755 μm x 145 μm, length:width ratio 5.2. Mean length of collar cells 250 μm, with collar-cell length: seed length ratio of 3.0. Other testa cells elongated, anticlinal walls finely undulated, outer cell walls convex. Operculum obtuse, funnel-like, with sunken hilum.

Seed Micromorphology: Anticlinal boundaries flat. Cuticular pattern consisting of long linear undulated striae.

Other Species Observed (Plate 1g,h)—Seed Structure and Micromorphology: Begonia radicans Velloso and B. in-
tegerrima Sprengel have seed structures that resemble those of B. solanthera in shape, general morphology, and cuticular pattern. Mean seed sizes are 1060 μm × 170 μm and 885 μm × 155 μm, respectively, and the length:width ratios are 1:6.2 and 1:5.7, respectively. The seeds of B. radicans also strongly resemble those of B. fruticosa of section Trendelenburgia. The periclinal walls of the testa cells are collapsed, with the exception of those at the chalaza of B. radicans.

Specimens Examined:
B. tegerrima var. tegerrima, BRAZIL: E. Pereira 606 (RB).
B. radicans, BRAZIL: H. Luederwaldt s.n. (SP); A.P. Duarte 3377 (RB).

1.3. Section Trendelenburgia (Klotzsch) A. DC.

PLATE 2a,f

The taxon Trendelenburgia was first described by Klotzsch as a genus in 1855 on the basis of one of the early Begonia collections by Ludwig Riedel in 1839. A. De Candolle (1864) changed the status to sectional level. Most probably the section is monotypic, with B. fruticosa as the type species.

The section is characterized by three-celled fruits with three equal-sized, very narrow wings and undivided placentas. The plants are slender-stemmed shrubs with a tendency to climb and with simple, pinnately veined leaves. Begonia fruticosa occurs in Argentina and southern Brazil.

TYPE SPECIES.—Begonia fruticosa A. DC. (Plate 2a,f).

Seed Structure: Seeds narrowly ellipsoid, extended micropylar and chalazal ends composed of bulging, air-filled cells. Testa cells covering central, embryo-containing part collapsed. One or both sides of seeds may be curved, rendering seeds J- or slightly S-shaped. Seed length 1310–1540 μm, width 160–200 μm, mean 1450 μm × 180 μm, length:width ratio 8.1 (slenderest seeds ever encountered in Begonia). Seeds of above described collection (Martins 8380) the biggest. Seeds of collections Herb. Brasil 1717, Kummrow 1636, a.d Herb. Brasil 850 with mean lengths of 1060 μm, 1005 μm, and 965 μm, respectively, and length:width ratios of 7.3, 5.4, and 6.3, respectively. Ratio of embryo-containing part to seed length 1:2.4. Collar cells strongly elongate, 275–380 μm in length, mean 325 μm, number in seed circumference about 10. Collar-cell length to seed length ratio 1:4.5. Longitudinal anticlinal walls of collar mostly undulated along entire length. Other testa cells of central part of seed also distinctly elongated and with undulated walls. Cells of operculum adjacent to collar elongated. Hilum sunken.

Seed Micromorphology: Anticlinal boundaries of operculum and chalaza sunken, those of central part of seed somewhat less so. Cuticle smooth, locally with faint, striate ornamentation, cuticle of central part of seed reflecting underlying pits. Larger pits present at bases of anticlinal walls.

Specimens Examined:
B. fruticosa, BRAZIL: R. Kummrow 1636 (MO); H.F. Martins 8380 (US); H. Schenck, Herb. Brazil 850, 1717 (B).

1.4. Section Scheidweileria (Klotzsch) A. DC.

PLATE 2b–e,g,h

The section Scheidweileria was described by Klotzsch as a genus in 1855. The section comprises six species, one of which, B. luxurians, is well known as a collector's plant. They are shrubs or small trees with compound, palmately veined leaves containing cystoliths and with large inflorescences that are dichotomous at the bases. The female flowers are characterized by five tepals, stigmas as helical bands with three turns, and undivided placentas. No seeds were available for B. semi-digitata Brade.

Most species of the section are limited to Brazil, but B. parviflora Poeppig & Endler has a wider distribution, extending to southern Central America.

TYPE SPECIES.—Begonia pentaphylla Walpers (Plate 2b,c).

Seed Structure: Seeds ellipsoid to narrowly ellipsoid, 600–680 μm in length, 220–300 μm in width, mean 640 μm × 265 μm, length:width ratio 2.4. Collar cells elongate, 180–280 μm in length, mean 225 μm, number in seed circumference about 12. Ratio of collar-cell length to seed length 2.8.

Longitudinal anticlinal walls of collar straight. Other testa cells polygonal, with straight anticlinal walls. Testa cells at chalaza with higher anticlinal walls and becoming deep due to collapse of outer periclinal walls. Chalaza usually flattened on one side, probably from contact with inner surface of fruit wall, resulting in cell crumpling. Border between collar and operculum abrupt. Operculum nipple-shaped, with collapsed cells.

Seed Micromorphology: Anticlinal boundaries flat. Cuticular pattern variable, that of collar cells mainly linear, that of remaining testa cells with shorter linear, undulated, or short zigzag striae. Locally, patches with less pronounced, mainly linear pattern.

Specimen Examined:

OTHER SPECIES OBSERVED (Plate 2d,e,g,h).—The seeds of other species observed are characterized by a flattened chalaza with deep testa cells as described above for B. pentaphylla, but they show distinct differences in seed lengths.

Seed Structure and Micromorphology: The seeds of B. parviflora are 270–350 μm in length, 155–180 μm in width, with a mean of 315 μm × 170 μm, and have a length:width ratio of 1.9. They most resemble the ordinary type of begonia seed.

The seeds of B. luxurians Scheidweiler and B. digitata Raddi are longer and closely resemble each other. Begonia luxurians seeds (Hoehne 2370) are 580–640 μm in length and 180–200 μm in width, with a mean of 610 μm × 185 μm and a length:width ratio of 3.3. The collection de Barros 1139 has smaller seeds, with a mean of 485 μm × 195 μm. Begonia digitata seeds are 595–655 μm in length and 165–210 μm in width, with a mean of 625 μm × 185 μm and a length:width ratio of 2.9. The operculum in B. digitata and B. luxurians is broadly
nipple-shaped, sometimes obturate, and has a sunken hilum (Sellow s.n. and Martinelli c.s. 8045, respectively). The seeds of B. incisoserrata A. DC. vary appreciably in size, being 370–500 μm in length and 170–215 μm in width, with a mean of 425 μm × 185 μm and a length : width ratio of 2.4.

The species of the section have straight or slightly curved antical walls except B. parviflora, in which all specimens locally have slightly undulated antical walls in the collar and testa. The species have a cuticular pattern as described for B. pentaphylla.

Specimens Examined:
B. digitata var. digitata, BRAZIL: Martinelli & Maas 3271 (U); Sellow s.n. (P); L.B. Smith cs. 6691 (US).
B. incisoserrata, BRAZIL: A.C. Brade 20096 (B); G. Hatschbach & R. Kummeran 45332 (US).
B. luxurians var. luxurians, BRAZIL: D. de Barros 1139 (B); F.C. Hooehe 2370 (B); G. Martinelli, Kautsky, & Leme 8045 (US).
B. parviflora, COLOMBIA: Ed. André K 284 (K); J. Cuatrecasas 11311 (US); Killip 7837 (US). ECUADOR: Holguer Lugo S 1808 (MO).

1.5. Section Ewaldia A. DC.

PLATE 3a–d
This taxon was described by Klotzsch (1855) as a genus and was reduced to a section by A. de Candolle in 1864. It was maintained as such by subsequent monographers (Warburg, 1894; Irmscher, 1925). The section comprises about 11 species. They resemble the species of section Scheidweileria in a number of characters, but they differ, among other characters, in the pinnate venation and in the shape and hairiness of the leaves. Except for the Venezuelan species B. boucena (Klotzsch) A. DC., the species are limited to Brazil.

TYPE SPECIES.—Begonia lobata Schott (Plate 3a).

Seed Micromorphology: Antical boundaries flat. Cuticular pattern coarse, that of chalazal cells with short linear or short undulated striae. Locally, patches with less pronounced, denser pattern.

Specimens Examined:
B. lobata, BRAZIL: G.L. Esteves c.s. CFCR 6028 (SP); G. Hatschbach 30073 (US), 36364 (MO).
B. aff. lobata, BRAZIL: P.J.M. Maas c.s. 3318 (U).

OTHER SPECIES OBSERVED (Plate 3b–d).—Seed Structure and Micromorphology: The seeds of B. rigida Linden ex Regel, B. scharffii Hook.f., and B. tomentosa Schott resemble those of B. lobata in the coarse cuticular pattern and the straight antical walls and boundaries. They differ, however, in a nipple-shaped operculum, smaller size, and the presence of a cuticular pattern with both short linear and short undulated to short zigzag striae. Mean seed sizes are 390 μm × 190 μm (B. rigida), 485 μm × 220 μm (B. scharffii), and 485 × 210 μm (B. tomentosa), with length : width ratios of 2.1, 2.2, and 2.3, respectively. The seeds of section Ewaldia, especially those of B. lobata, resemble the seeds of section Scheidweileria in shape, in size, and in having a somewhat massive operculum.

Specimens Examined:
B. scharffii, BRAZIL: Palacios-Cuezo 2930 (US).
B. tomentosa var. tomentosa, BRAZIL: A.C. Brade 18572 (US).

1.6. Section Enita Brade
PLATE 3e,f–k
The species now constituting section Enita have a rather complicated taxonomic history. Klotzsch (1855) attributed the species then described, together with a number of species now mainly in section Pritzelia, to his genus Wageneria. A. de Candolle (1861) transferred this genus to Begonia section Wageneria. Warburg (1894) merged Wageneria with the large section Pritzelia, and this opinion was shared by Irmscher (1925). Brade (1945) established Enita as a subsection and later raised it to sectional level (Brade, 1957). The correct name of the section should be Wageneria Klotzsch, with B. fagifolia Hort. Petrop. ex Otto & Dietrich as type species (Doorenbos et al., 1998). The section comprises probably 10 species. The species of section Enita deviate from those of section Pritzelia by having stamens with filaments slightly united below and anthers usually much shorter than the filaments, and by having cylindrical seeds crowned with a group of larger cells at the chalaza. Moreover, they are climbing semishrubs with stems that often produce adventitious roots at the nodes and that have symmetrical or subsymmetrical, pinnately or palmately veined leaves.

All species are limited to Brazil except B. glabra Aublet, which has a wider distribution, occurring in the West Indies and from Mexico to Colombia and Ecuador.

TYPE SPECIES.—Begonia convolvulacea (Klotzsch) A. DC. (Plate 3e).

Seed Structure: Seeds narrowly ellipsoid, micropylar and chalazal ends differing, 635–705 μm in length, 180–215 μm in width, mean 675 μm × 195 μm, length : width ratio 3.4. Collar cells elongate, 130–475 μm in length, mean 275 μm, number in seed circumference about 11. Ratio of collar-cell length to seed length 2.4.

Longitudinal antical walls of collar and other testa cells usually straight, sometimes slightly undulated. Other testa cells
also elongated. Chalazal end of seed flattened and with cells with higher anticlinal walls. These cells may become deep from collapse of outer periclinal walls or somewhat inflated from bulging of outer walls. Operculum oblate, with sunken hilum.

**Seed Micromorphology:** Anticlinal boundaries usually flat but sunken at boundary of collar and operculum and at chalaza. Cuticular pattern weakly developed, with linear or short linear striae, more distinct at operculum. Locally, patches without ornamentation.

**Specimens Examined:**
B. convolvulacea, BRAZIL: G. Hatschbach 9193 (B, L); H. Schenck, Herb. Brazil 858 (B).

**Other Species Observed (Plate 3f–k).—Seed Structure:** The seeds of B. epibaterium Martius ex A. DC., B. fagifolia, and B. glabra are quite similar in general shape to those of B. convolvulacea, but they may vary in the condition of the chalazal and micropylar ends, cells of which may be shriveled or inflated.

Unfortunately, only immature seeds of B. smilacina A. DC. were available; however, their morphology corresponds to that of other species of section Enita. No seeds were available of B. inconspicua Brade, but the drawing of Brade (1945, pl. 4.12) shows the seed type particular to section Enita.

In all specimens of the species observed, the chalazal side is flattened, probably from contact with the fruit wall, except in B. epibaterium (Scott Mori & Forbes Benton 12856), which has a more tapering, often somewhat asymmetric chalaza. Seed size in B. epibaterium tends to be a little smaller, as in B. convolvulacea. The mean seed size varies from 495 μm × 170 μm in B. epibaterium (Dos Santos 3408) to 660 μm × 150 μm in B. glabra (Laurito 8172). The length:width ratio in section Enita varies between 2.9 and 4.4. In all specimens observed the anticlinal walls may be undulated; however, some variation exists in the presence and extent of the undulations.

**Remarks:** The seeds of the different collections of the widespread species B. glabra vary in respect to the above-mentioned characters. The specimens from Surinam differ by having conspicuous chalaza with inflated cells, which make the chalaza even broader than the central part of the seed. The cuticular structure of the chalazal cells is more pronounced, with a more randomly orientated zigzag ornamentation and distinct patches with a confluent cuticular pattern.

The seeds of the collection from Cuba have few collar cells (mean=8), with a mean length of 315 μm, and the ratio of collar-cell length to seed length is 2.0. This may be compared with, for instance, the collection from Costa Rica, the seeds of which have about 10 collar cells in the seed circumference. The collar cells have a mean length of 195 μm, and the ratio of collar-cell length to seed length is 3.4.

Our samples of B. glabra var. amplifolia (A. DC.) L.B. Smith & B.G. Schubert and B. glabra var. cordifolia (C. DC.) Irmscher do not show specific characters and more resemble B. convolvulacea in having less-inflated chalazal cells.

**Specimens Examined:**
B. epibaterium var. epibaterium, BRAZIL: Dos Santos 3408 (US); Scott Mori & Forbes Benton 12856 (US).
B. fagifolia, BRAZIL: Brade 19144 (B); Gaudichaud 1060 (P).
B. glabra var. amplifolia, COLOMBIA: E.P. Killip 7722 (K).
B. glabra var. cordifolia, CULTIVATED: van Veldhuizen 370 (WAG).
B. glabra var. glabra, COLOMBIA: T.A. Sprague 403 (K).
SURINAM: Indigen 270 (U); H.S. Irwin c.s. 54738, 54818 (U).

1.7. **Section Pritzelia** (Klotzsch) A. DC.

**PLATES 4, 5a,b**

The section is characterized by male flowers with four tepals, free filaments, and anthers longer than the filaments and by female flowers with five tepals and undivided placenta. The leaves contain cystoliths. The section comprises about 100 species and is the largest section in Brazil. Only a few species of this section have a wider distribution. The section includes the former section Saueria A. DC.

**Species Observed.**—Seeds of 19 species have been observed using SEM. With a few exceptions, the seed structure corresponds with the ordinary begonia seed type. The seeds of the species differ in shape, size, and micromorphology to some extent.

**Seed Structure:** The seed shape is ellipsoid to slightly narrowly ellipsoid. The mean seed size of the section type, B. dietrichiana Irmscher, is 350 μm × 195 μm, with a length:width ratio of 1.8. Within the section the mean seed length varies from 310 μm in B. acida Vellozo to 620 μm in B. angulata Vellozo var. serrana Brade, and the length:width ratio varies from 1.7 to 2.6, respectively.

The anticalinal walls of the testa cells are straight or almost straight but are somewhat curved to slightly undulated in B. paranaensis Brade. The operculum is mostly nipple-shaped, sometimes broadly nipple-shaped, or obtuse in B. coccinea Hooker.

**Seed Micromorphology:** The anticalinal boundaries are flat except for those of B. grisea A. DC. and B. itaguassuensis Brade, which have sunken and locally sunken anticalinals, respectively. The majority of the seeds have a fine, dense cuticular pattern of mainly short linear striae, more zigzag in B. epispila Brade and B. paranaensis. In B. grisea the cuticle is almost without ornamentation. Five species deviate in cuticular sculpture. Begonia acida, B. hispida Schott, and B. sanguinea Raddi have a more pronounced and coarse, mainly zigzag pattern. In B. angulata and B. coccinea the cuticular pattern is very pronounced, consisting of long zigzag, sometimes even pleat-like, striae. The seeds of B. itaguassuensis also have a fine, dense cuticular pattern; however, they differ from the seeds of all other observed Pritzelia species by having anticalinal walls that are
more thickened and elevated, are straight and form a distinct polygonal pattern at the outside, and are undulated, with pockets at their bases.

Begonia grisea and B. paranaensis resemble each other in shape and testal pattern. The seeds of B. bradei Irmscher, B. crispula Brade, B. dietrichiana, and B.olsoniae Smith & Schubert also resemble each other in some respects. The seeds of B. itupavensis Brade most resemble those of B. hookerana Gardner (Occchiioni 4788) of section Steineria.

Remarks: The monotypic section Saueria A. DC. was eliminated by the placement of the Colombbian type species B. sulcata Scheidweiler in Otto & Dietrich into synonymy with the Venezuelan species B. dichotoma Jacquin of section Pritzelia by L.B. Smith (1973). Although unfortunately no seeds of B. dichotoma were at our disposal, the seeds of B. sulcata quite closely resemble those of some other species of section Pritzelia from Brazil, e.g., B. angulata.

Specimens Examined:
B. acida, BRAZIL: cult., Boone-Hahn 108 (WAG); cult., Hort. bot. Liège.
B. angulatus var. angularis, BRAZIL: D.R. Hunt 6470 (K).
B. angulata var. angulata, BRAZIL: Hatschbach 8831 (L).
B. angulata var. serrana, BRAZIL: Brade 17531 (U).
B. coccinea, BRAZIL: Burchell 2194 (P); cult., Ziesenhenne s.n.
B. crispula, BRAZIL: cult., Boone-Hahn 13 (WAG).
B. dichotoma, COLOMBIA: cult., Boone-Hahn 25 (WAG, as B. sulcata).
B. dietrichiana, BRAZIL: A.P. Duarte 378 (US).
B. epipsila, BRAZIL: cult., Boone-Hahn 27 (WAG).
B. grisea, BRAZIL: St. Hilair B 2027 (P); H.S. Irwin c.s. 27654 (MO).
B. hispida var. hispida, BRAZIL: Bailey & Bailey 710 (L); Vau-thier 542 (P).
B. huegelii (Klotzsch) ex A. DC., BRAZIL: Altamira & Wolter 11 (U).
B. itagussuensis, BRAZIL: A. Lourteig 3236 (P).
B. itupavensis, BRAZIL: Hatschbach 11713 (U).
B. olsoniae, BRAZIL: cult., van Veldhuizen 408 (WAG); E. Pereira 307 (RB, as B. vellozoana Brade, paratype).
B. paranaensis, BRAZIL: Hatschbach 8941 (L).
B. petasitifolia Brade, BRAZIL: cult., van Veldhuizen 997 (WAG).
B. reniformis Dryander, BRAZIL: Luederwaldt & Fonseca 18031 (B); Ynes Mexia 5148 (P).
B. sanguinea, BRAZIL: Bailey & Bailey 706 (L).

1.8. Section Philippomartia A. DC.

PLATE 5c–e

According to Irmscher (1953), the species of this section closely resemble those of section Pritzelia except for some stigmatic characters and for a ring of tentacle-like processes at the top of the petioles. Such a ring also is known in a number of species of Pritzelia and in some other sections. The section comprises two or three species, B. leptophylla Taubert, B. membranacea A. DC., and B. neglecta A. DC. The taxonomic position of B. leptophylla is questionable (Doorenbos et al., 1998). No seeds of B. neglecta were available.

Species Observed:—Seed Structure: The seeds of B. leptophylla and B. membranacea resemble each other and agree in many characters with those of species in section Pritzelia, such as B. dietrichiana. The mean seed length of both species lies between 300 µm and 360 µm. The testa cells are polygonal, with straight anticinal boundaries, and the operculum is nipple-shaped.

Seed Micromorphology: The cuticular pattern is fine and dense; the striae are short linear in B. leptophylla and are zigzag in B. membranacea.

Specimens Examined:
B. leptophylla, BRAZIL: A. Mo 4331 (MO).
B. membranacea, BRAZIL: H.M. Curran 170 (US); Ex herb. horti Petropolitani Brasilia Castelnuovo (K).

1.9. Sections Steineria (Klotzsch) A. DC. and Bradea Toledo PLATES 5f–n. 6a,b

Section Bradea was separated from section Steineria by Toledo in 1946 on the basis of differences in the staminate flower. The sections Steineria and Bradea comprise about four species (seeds of B. caraguata-tubensis Brade were not available) and 10 species, respectively. The two sections cannot be distinguished from each other on the basis of seed characters.

The species of both sections are restricted to Brazil, with the exception of the questionable species B. opuliflora Putzeys from the former New Granada, which is based on a drawing of a horticultural specimen.

Type Species. Section Steineria.—Begonia hookerana Gardner (Plate 5f,j).

Seed Structure: Seeds narrowly ellipsoid to ellipsoid. Mean seed size 465 µm x 180 µm, length:width ratio 2.6. Collar cells elongated, other testa cells polygonal, with straight or slightly curved anticinal walls. Operculum nipple-shaped.

Seed Micromorphology: Anticinal boundaries flat. Cuticular pattern consisting of mainly short linear striae. Seeds of collection Burchell 2539 somewhat smaller, with locally undulated anticinal walls and fainter cuticular pattern.

Specimens Examined:
B. hookerana, BRAZIL: Burchell 2539 (K); P. Occhioni 4788 (US).

Other Species Observed, Section Steineria (Plate 5g,f)—The seeds of B. arborescens Raddi var. arboriscens and B. oxyphylla A. DC. resemble those of B. hookerana, especially collection Burchell 2539. Their mean seed sizes vary between 330 µm and 415 µm. They all show locally undulated anticinal walls with pockets at their bases and thin outer anticinal walls reflecting many small pits. The cuticular pattern of
both species and of the variety B. arborescens var. confertiflora A. DC. show some minor differences.

Specimens Examined:
B. arborescens var. arborescens, BRAZIL: M. Clausen 63 (P); Grisebach s.n. (K); J. Miers 3291 (K).
B. arborescens var. confertiflora, BRAZIL: Gardner 602 (K, type).
B. oxyphylla, BRAZIL: Inh. Vien s.n. (1828) (K).

Type Species, Section Bradea.—Begonia rufosericea Toledo (Plate 5m).

Seed Structure and Micromorphology: Seeds closely resembling those of (especially) B. arborescens in general aspect and in above-mentioned characters, except for less-pronounced undulation of anticlinal walls.

Specimens Examined:
B. rufosericea, BRAZIL: Oswaldo Hanro s.n. (B); cult., van Veldhuizen 496 (WAG).

Other Species Observed, Section Bradea (Plates 5h,k,n, 6a,b).—Some other seed collections of section Bradea observed, especially those of B. bidentata Raddi and B. polyandra Immscher, resemble B. rufosericea. They differ by having curved anticlinal walls and a more distinct cuticular pattern of zigzag striae. The seeds of B. bidentata collection Riedel s.n., B. parvifolia Schott, and B. dentati1oba A. DC. show a more reticulate character set.

Specimens Examined:
B. bidentata var. bidentata, BRAZIL: A. Glaziou 11873 (K); G. Peckolt 75 (B); E. Pereira 287 (B); Riedel s.n. (U).
B. dentati1oba, BRAZIL: L.B. Smith 1935 (K).
B. parvifolia, BRAZIL: d’Allezette s.n. (L); A. Glaziou 15388 (K); Brasilia Schott s.n. (B).
B. polyandra, BRAZIL: Herb. Hieronymus s.n. (B, type).

1.10. Section Tetrachia Brade

Plate 6c,g

The monotypic section Tetrachia was established by Brade in 1945 on the basis of his newly described species B. quadri1ocularis. This species was put into synonymy with B. egregia by Smith and Schubert (1955). The section is characterized by ovaries with four locules by the presence of four styles and four-winged capsules. The number of tepals of the staminate and pistillate flower is two and six, respectively. The species is restricted to the state of Rio de Janeiro, Brazil.

Type Species.—Begonia egregia N.E. Brown (Plate 6c,g).

Seed Structure: Seeds ellipsoid, 500–550 µm in length, 250–300 µm in width, mean 530 µm × 275 µm, length:width ratio 1.9. Collar cells 155–230 µm in length, mean 190 µm, number in seed circumference about 12. Ratio of collar-cell length to seed length 1: 2.8. Tepals cells polygonal, anticlinal walls somewhat thickened, straight, slightly curved toward collar. Operculum broadly nipple-shaped.

Seed Micromorphology: Anticlinal boundaries flat. Cuticular pattern consisting of long linear and long zigzag striae, the latter locally more pronounced.

Remarks: Seeds resemble those of B. itagauassensis of section Pritzelia in the more thickened, straight, and elevated anticlinal walls.

Specimens Examined:
B. egregia, BRAZIL: J. Santos Lima s.n. (US, as B. quadri1ocularis Brade, isotype); cult., Boone-Hahn 1 (WAG).

1.11. Section Gaeridia (Klotzsch) A. DC.

Plate 6d–f,h

The placenta provides the most obvious character for this section. The placenas are two-parted, and the two lobes in each locule cling together and bear ovules on their outer sides only. The section contains about six species, three of which, B. maculata Raddi, B. corallina Carriere, and B. undulata Schott, were observed.

Type Species.—Begonia maculata (Plate 6e,f), the seeds of which are to some extent characteristic and deviate in size and shape from the two other species observed.

Seed Structure: Seeds elliptic, sometimes narrowly elliptic. Mean seed size 565 µm × 240 µm, length: width ratio 2.4. Collar cells relatively long, mean length 290 µm. Ratio of collar-cell length to seed length 1.9. Tepals cells adjacent to collar also elongated. Operculum long nipple-shaped. Anticlinal walls mainly straight.

Seed Micromorphology: Anticlinal boundaries flat, locally sunken. Cuticular pattern short zigzag.

Specimens Examined:
B. maculata var. maculata, BRAZIL: Gentry & Zardini 49513 (MO); Maas & Carauta 3149 (U).

Other Species Observed.—Seed Structure and Micromorphology: The seeds of B. corallina and B. undulata are smaller, with a mean seed length of 495 µm and 460 µm, respectively.

Specimens Examined:
B. corallina, CULTIVATED: Boone-Hahn 114 (WAG).
B. undulata, BRAZIL: Gaudichaud 1067 (P); cult., Hort. Bogoriensis 6071 AB (L).

1.12. Section Latistigma A. DC.

Plate 6j–l,n

The species of this section are characterized by the presence of five tepals in the pistillate flowers and by broad, lobed styles. The section contains three species, B. aconitifolia A. DC. and B. platani1ofilia Schott from Brazil, and B. leatherrnaniae O’Reily & Karegeannes from Bolivia.

Type Species.—Begonia aconitifolia (Plate 6j).

Seed Structure: Seeds ellipsoid, mean seed size 440 × 250 µm, length:width ratio 1.8. Tepal cells polygonal, with straight or slightly curved anticlinal walls. Anticlinal walls with more or less distinct pockets at bases.
Seed Micromorphology: Cuticular pattern fine and very dense, consisting of mainly short zigzag striae.

Specimens Examined: B. aconitifolia, BRAZIL: Glaziou 13389 (B).

OTHER SPECIES OBSERVED.—Seed Structure and Micromorphology: The seeds of B. platanifolia and B. leathermaniae closely resemble those of B. aconitifolia, differing mainly by their somewhat smaller size.

Specimens Examined: B. leathermaniae, BOLIVIA: O. Kuntze s.n. (B); M. Moraes 1056 (US).
B. platanifolia var. platanifolia, BRAZIL: Creagh s.n. (B); G. Hatschbach 46298 (US).

1.13. Section Pereira Brade

PLATE 6m

This monotypic section is characterized by two-lobate broad stigmata that are almost kidney-shaped and cyamatum-like.

TYPE SPECIES.—Begonia edmundoi Brade, limited to Brazil.

Seed Structure and Micromorphology: Seeds conforming to ordinary seed type, not showing distinguishing characters. Mean seed size 460 x 230 μm, length:width ratio 2.0. Anticlinal walls straight and relatively thin. Cuticular pattern consisting of short linear to short zigzag striae.

Specimen Examined: B. edmundoi, BRAZIL: E. Pereira 366 (B, cotype).

2. SECTIONS MAINLY CONFINED TO THE ANDERG AND GUIANAN REGIONS

Of the 12 Andean sections, five (Casparya, Gobenia, Hydristyles, Rossmannia, Warburgina) have a characteristic seed structure that distinguishes them from all other Neotropical sections.

2.1. Section Casparya (Klotzsch) A. DC.

PLATES 7-9

Section Casparya has a very complicated taxonomic history. Shortly after its establishment as a genus by Klotzsch (1855), A. De Candolle (1864) extended it by including in it Klotzsch’s genera Isopteryx, Sassea, and Stibadotheca and his newly described sections Aetheopteryx and Andiphila. Warburg (1894) reduced the genus Casparya to sectional level and reduced De Candolle’s sections to subsections, actions that were later accepted by Irmscher (1925). Moreover, he inserted Isopteryx in Andiphila.

Smith and Schubert (1955) also merged the five species of the former genus Begoniella with section Casparya.

The section is characterized by bifid, or many-, or irregularly branched styles and by triquetrous fruits that are not winged but have each of the edges terminating in a horn. The capsule dehisces at the edges. The plants are mostly erect semishrubs and usually grow above 2000 m elevation, especially in the Andean region of Colombia and Ecuador and in Venezuela. The section comprises about 40 species.

Begonia urticae Group

Begonia urticae LINNAEUS F. (Plate 7a,b,d).—Type species of section Casparya.

Seed Structure: Seeds narrowly ellipsoid, micropylar ends flattened. Seed shape slightly varying from ellipsoid to more ovoid, with greatest width in middle or more to micropylar or chalazal end. Length 695–780 μm, width 370–390 μm, mean 745 μm x 385 μm. Length:width ratio 1.9.

Collar cells relatively short, 90–155 μm in length, mean 130 μm, number in seed circumference about 15. Ratio of collar-cell length to seed length 1:5.7. Longitudinal walls of collar undulated over entire length. Other tests cells polygonal, mostly not arranged in distinct rows. Anticlinal walls strongly undulated. Operculum nipple-shaped, sometimes almost flat. Ring of cells bordering collar slightly deepened.

Seed Micromorphology: Anticlinal boundaries straight. Cuticular pattern rough, with relatively thick, linear to short linear or slightly undulated striae. No distinct patches.

Remarks: The 10 samples of B. urticae studied, the most common and most widely distributed species of section Casparya, show some variation in size and micromorphology.

The seeds of the collections Schultes & Villarreal 7786, Dryander 1694, Bouman s.n., Bonpland s.n., and Irally 192 closely resemble those of the above-described collection Harling et al. 20465. The mean seed size varies from 675 μm x 335 μm (Schultes & Villarreal 7786) to 785 μm x 430 μm (Irally 192). The length:width ratio varies from 1.7 (Dryander 1694) to 2.0 (Schultes & Villarreal 7786). The collections Bohlin 975 (originally described as B. urticae var. retusa Smith & Schubert), Cuatrecasas 23315, de Escobar c.s. 8521 (originally described as B. antioquensis (A. DC.) Warburg), and Scott Hoover 442 deviate from the above-mentioned ones by having a smaller seed size and a more conspicuous undulation of the anticinal cell walls. The mean seed size in collections Cuatrecasas 23315 and Scott Hoover 442 are 585 μm x 320 μm and 605 μm x 315 μm, respectively. In both collections, however, the cuticle has undulated striae of normal thickness. The collection Scott Hoover 442 deviates by having larger collar cells with straighter longitudinal anticinal walls. Mean length of the collar cells is 185 μm, with a collar-cell length to seed-length ratio of 1:3:3.

Specimens Examined:
B. species, ECUADOR: van der Werff & Palacios 9135 (MO);
Scott Hoover & Wormley 1822 (MO).
**B. urticae, COLOMBIA: M.A. Bonpland s.n. (P); F. Bouman s.n. (AMD); Cuatrecasas 23515 (US); E. Dryander 1694 (US); de Escobar, Velasquez, & Marulanda 8521 (US); W. Irally 192 (K); W. Scott Hoover 442 (US); Schultes & Villarreal 7786 (US); ECUADOR: J.E. & M. Bohlin 975 (US); Harling et al. 20465 (US).**

**OTHER SPECIES OBSERVED (Plate 7c–e).—Seed Structure and Micromorphology:** The seeds of *B. fuchsiflora* (A. DC.) A. Baranov & F.A. Barkley, *B. gamolepis* L.B. Smith & B.G. Schubert, *B. longirostris* Bentham (Harling & L. Andersson 11608), and *B. species* (Scott Hoover & Wormley 1771) resemble those of *B. urticae* collection Bohlin 975 in size and in the strongly undulated anticlinal walls of both the testa and cotter cells. Mean seed size varies from 545 μm × 310 μm in *B. gamolepis* to 630 μm × 375 μm in *B. fuchsiflora*. All collections have a cuticle with mainly undulated striae of normal thickness except for collection Scott Hoover & Wormley 1771, which has a faint double structure.

**Specimens Examined:**

*B. fuchsiflora*, ECUADOR: M.T. Madison 6854 (US); W. Scott Hoover 515 (MO).

*B. gamolepis*, COLOMBIA: Barkley & Araque M. 185094 (US); Killip & A.C. Smith 16037 (B).

*B. species*, ECUADOR: Scott Hoover & Wormley 1771 (MO).

**Begonia ferruginea Group**

*Begonia ferruginea* LINNAEUS F. (Plate 7h–k).—Seed Structure: Seeds narrowly obovate to obtriangular, micropylar end flattened, becoming acute at chalazal end. Length 770–960 μm, width 265–325 μm, mean 880 μm × 290 μm. Length: width ratio 3.0. Number of collar cells in seed circumference about 14. Longitudinal walls of collar cells straight, sometimes slightly undulated. Other testa cells often elongated, with undulated anticlinal walls, cells of chalazal part more polygonal. Operculum nipple-shaped.

**Seed Micromorphology:** Anticlinal boundaries flat. Cuticular ornamentation conspicuous, more or less plicate, composed of long, undulated foldings forming loose structure. Locally, patches with long, parallel striae.

**Remarks:** The seeds of two other collections are smaller and more variable in shape than the above-described collection (Langenheim 3387). Mean seed size is 775 μm × 345 μm in collection Grubb et al. 534 and is 710 μm × 345 μm in collection Steyermark & Dunsterville 100784, with length: width ratios of 2.2 and 2.1, respectively. The seeds are ellipsoid, with rounded or more acute chalazal ends. Seeds of *B. ferruginea var. dilatata* Smith & Schubert are narrowly ellipsoid, with a mean seed size of 700 μm × 240 μm and a length: width ratio of 2.9. There are about 16 collar cells in the seed circumference, and the chalazal end is rounded or somewhat acute. The cuticular plicas and foldings are long and are undulated or somewhat zigzag.

**Specimens Examined:**

*B. ferruginea* var. dilatata, COLOMBIA: H. Garcia-Barriga 12053 (US).

*B. ferruginea* var. ferruginea, COLOMBIA: Grubb, Curry, & Fernandez-Perez 534 (US); J.H. Langenheim 3387 (US); Steyermark & Dunsterville 100784 (US).

*B. species*, COLOMBIA: F.A. Barkley 38c120 (US).

**Begonia trispathulata Group**

**Seed Micromorphology:** Anticlinal boundaries flat. Cuticle with so-called double structure: more elevated, short zigzag to star-shaped thick foldings and irregular, short zigzag to short linear underlying ornamentation. Locally, patches of labyrinth-like structure.

**Specimens Examined:**

*B. trispathulata*, VENEZUELA: L. Goldsmith 169 (VT); N. Ramirez 349 (MO); S.S. Tillett 739–585 (P).

**OTHER SPECIES OBSERVED (Plate 8c–l).—Seed Structure and Micromorphology:** A number of species occurring in and mostly endemic to Venezuela resemble *B. trispathulata* in seed structure. All species are characterized by cuticles with a distinct double structure. *Begonia brevipeptala* Warburg, B. mariae L.B. Smith, and B. trujillensis L.B. Smith agree in seed size and shape. In B. trujillensis the more elevated elements of the cuticular double structure are short undulated to short zigzag or star-shaped, in B. brevipeptala they are short zigzag or star-shaped, whereas in B. mariae they are mainly star-shaped. The star-shaped ornaments often show a central depression.

The seeds of *B. lipolepis* L.B. Smith differ in some characters. The seeds are quite variable in shape, with a tendency to a tapering chalazal end. The mean seed size is 575 μm × 300 μm, with a length: width ratio of 1.9. The anticlinal walls are less undulated and are sometimes almost straight to slightly curved. The cuticular double structure consists of short zigzag to star-shaped elements.

The seeds of *B. toledana* L.B. Smith & B.G. Schubert have a mean size of 500 μm × 300 μm. The anticlinal walls are distinctly undulated. The double structure is short undulated to short zigzag.

The seeds of *B. formosissima* Sandwich have a mean size of 635 μm × 395 μm. The anticlinal walls are less distinctly undulated. The double structure is composed of relatively dense,
mainly short zigzag elevations that obscure the underlying granular pattern.

**Specimens Examined:**
B. brevipedata var. brevipedata, VENEZUELA: F.J. Breteler 3468 (US); L. Goldsmith 160 (VT); Steyermark & Melhin 109935 (U).
B. formosissima, VENEZUELA: L. Goldsmith 166 (VT); Ruiz-Teran & Figueiras 9306 (US).
B. lipolepis, VENEZUELA: L. Goldsmith 167 (VT).
B. mariae, VENEZUELA: L. Goldsmith 163 (VT).
B. toledana var. toledana, COLOMBIA: Killip & A.C. Smith 20270 (B). VENEZUELA: Steyermark & Dunsterville 100604 (K).
B. trujillensis, VENEZUELA: L. Goldsmith 168 (VT); S.S. Tillett 739-611 (US).

**Begonia pectennervia Group**

**Seed Micromorphology:** Anticinals crossed by radiating longitudinal striae leaving “central field” of randomly orientated, small zigzag cuticular foldings of irregular thickness and elevation.

**Remarks:** The seeds of collection Holm-Nielsen et al. 26762 differ slightly from the above-described collection (Holm-Nielsen et al. 26438) by having less-shallow testa cells and by having a cuticular ornamentation of short linear to short zigzag striae, sometimes with a faint double structure.

**Specimens Examined:**

**Other Species Observed** (Plate 9a–g).—Seed Structure and Micromorphology: The seeds of B. colombiana Smith & Schubert, B. killipiana Smith & Schubert, B. longirostris (Lugo 4699), and B. trispathulata (Steyermark 103480) resemble those of *B. pectennervia* in their broad anticinal and shallow outer pericinal walls. The mean seed size varies from 440 µm × 275 µm in *B. trispathulata* to 655 µm × 470 µm in *B. killipiana*. The number of collar cells in the seed circumference varies from about 17 in *B. colombiana* to 22 in *B. killipiana*. The seeds of *B. killipiana* are characterized by short collar cells that vary in length from 65 µm to 130 µm, with a mean of 90 µm. The testa cells of *B. killipiana* and *B. longirostris* have a cuticular pattern similar to that of the central field, with short zigzag to star-shaped foldings. *Begonia colombiana* has a very dense pattern of short zigzag and short undulated striae; *B. trispathulata* has a double structure of linear, undulated, or zigzag striae of varying length. The star-shaped cuticular foldings in *B. killipiana* occasionally have a central depression. The seeds of *B. killipiana* collections Killip 7994 and W.S. Hoover 463 resemble those of *B. antioquensis* collection Luteyn 12265, described below, especially in their micromorphological characters. The collar cells of *B. killipiana* and *B. longirostris* are or tend to be very short; those of *B. trispathulata* are relatively short. Of these four species, the seeds of *B. killipiana* most resemble those of *B. hexandra*, described below.

**Specimens Examined:**
B. colombiana, COLOMBIA: Schultes & Villarreal 7758 (US).
B. killipiana, COLOMBIA: Killip 7994 (US); W. Scott Hoover 27, 463 (US).
B. longirostris, ECUADOR: Lugo 4699 (MO).
B. trispathulata, VENEZUELA: Steyermark 103480 (US).

**Begonia antioquensis**

* Begonia antioquensis (A. DC.) Warburg (Plate 9f).—Seed Structure: Seeds ellipsoid, without distinct differentiation between operculum and collar, 510–600 µm in length, 295–360 µm in width, mean 560 µm × 325 µm, length:width ratio 1.8. No characteristic collar cells; all testa cells more or less isodiametric or somewhat irregular, not distinctly longitudinal elongated. Anticinal walls pronounced, with rather obscure undulation, broader distally than proximally, and resembling rope netting. Micropylar end of seed rounded, without distinct hilum and micropyle.

**Seed Micromorphology:** Anticinal boundaries obscured, anticinal cells rough cross-hatched. Cuticle distinctly double-structured. Elevated parts, about 12 per cell, irregularly round or star-shaped, with central depression and interconnected by radiating linear cuticular striae.

**Specimens Examined:**
B. antioquensis, COLOMBIA: J.L. Luteyn 12265 (US).

**Begonia hexandra**

* Begonia hexandra Irmscher (Plate 9h).—Seed Structure: Seeds broadly ellipsoid, without distinct borderline between operculum and collar, 630–680 µm in length, 505–565 µm in width, mean 660 µm × 540 µm, length:width ratio 1.2. No distinct differentiation between collar cells and other testa cells. Cells surrounding micropylar-hilar region somewhat more elongated, over 30 cells in circumference. Shape of testa cells irregular due to strongly undulated anticinal walls. Anticinals relatively broad, without boundary. Cell pattern difficult to recognize due to shallowness of outer pericinal walls. Micropyle a small, irregular bulge without distinct exostome and hilar scar.
Seed Micromorphology: Cuticular pattern, if present, reduced, with longitudinal striae.

Specimen Examined:
B. hexandra, COLOMBIA: E.L. Core 1500 (US).

Begonia diversistipulata Group

Begonia diversistipulata IRMSCHER (Plate 9j).—Seed Structure: Seeds ellipsoidal, with flat operculum, 345–435 µm in length, 270–315 µm in width, mean 390 µm × 295 µm, length:width ratio 1.3. Collar cells 80–150 µm in length, mean 110 µm, number in seed circumference about 13. Ratio of collar-cell length to seed length 1:3.5. Testa cells polygonal, arranged in rows. Anticlinal walls relatively thin, straight or slightly undulated. Micropyle almost not protruding.

Seed Micromorphology: Anticlinal boundaries flat. Cuticular pattern consisting of rather loose, short, undulated striae to more condensed, short zigzag striae.

Specimen Examined:
B. diversistipulata, COLOMBIA: Giacometto 11 (B).

Other Species Observed (Plate 9k).—The seeds of B. umbellata H.B.K. resemble those of B. diversistipulata in the thin, straight or almost straight anticlinal walls and a simple cuticular pattern of short linear to short undulated striae. The seeds, however, differ in size and in the number of collar cells. Mean seed size is 590 × 350 µm with a length:width ratio of 1.7. The number of collar cells in the seed circumference is about 17.

The collection Scott Hoover 443 differs from the above-described collection (Killip & Hazen 9165) by having a denser cuticular pattern, consisting of a double structure of mainly long zigzag striae.

Specimen Examined:
B. umbellata, COLOMBIA: Killip & Hazen 9165 (US); W. Scott Hoover 443 (US).

Ungrouped Species

Species Observed (Plate 9l–n).—The seeds of Begonia montana Warburg, B. raimondi Irmscher, B. hirta (Klotzsch) Smith & Schubert, and one collection of B. formosissima (Lopez-Figueiras & Dugarte 29409) could not be incorporated into one of the groups of section Casparys described above.

Seed Structure and Micromorphology: Begonia montana and B. formosissima have, respectively, mean seed sizes of 545 µm × 340 µm and 565 µm × 360 µm and mean collar-cell lengths of 130 µm and 115 µm. Both have undulated anticlinal walls; those of the collar are straighter.

The cuticular pattern is granular in B. montana and is granular to short zigzag and more uneven in elevation in B. formosissima.

The mean seed sizes in B. raimondi and B. hirta are 790 µm × 395 µm and 725 µm × 385 µm, respectively. Mean collar-cell length in B. raimondi is 185 µm. The cuticular ornamentation in B. raimondi consists of dense, short undulated striae; in B. hirta it is more granular.

Specimens Examined:
B. formosissima, VENEZUELA: Lopez-Figueiras & Dugarte 29409 (US);
B. hirta var. hirta, PERU: R.J. Seibert 2385 (US).
B. montana, VENEZUELA: Funck & Schlim 1044 (P, isotype);
H. Humbert 26725 (US).
B. raimondi, PERU: A. Raimondi 2982 (B).

2.2. Section Rossmannia (Klotzsch) A. DC.

Plate 10a–c

The taxon Rossmannia was first described by Klotzsch as a genus in 1855 and was transferred to sectional level by A. De Candolle in 1864. The monotypic section is characterized by pistillate flowers with two-parted placentas and by fruits with two very small wings and one large, subascending wing up to 40 mm long, covered by two large, persistent bracteoles. Begonia rossmanniae is a climbing shrub that occurs in humid forests of Ecuador, Peru, and Colombia.

Type Species.—Begonia rossmanniae A. DC. (Plate 10a–c).

Seed Structure: Seeds narrowly ellipsoidal, micropylar and chalazal ends extended, one or both sides often curved, rendering seeds J- or slightly S-shaped. Micropyel end of seed composed of uncollapsed, air-filled cells, chalazal end tapering, with elongated, collapsed cells. Length 645–710 µm, width 135–150 µm, mean 675 µm × 140 µm, length:width ratio 4.8. Ratio of embryo-containing part of seed to total length of seed 1:2.8. Collar cells 105–225 µm in length, mean 160 µm, number in seed circumference about 9. Ratio of collar-cell length to seed length 1:4.2. Longitudinal anticlinal walls of collar and adjacent cells straight or slightly undulated, those of operculum and chalaza always straight. Cells of operculum adjacent to collar elongated. Hilum sunken.

Seed Micromorphology: Anticlinal boundaries straight, those of operculum sunken. Cuticle with linear to short linear pattern. Operculum with long linear striae, often running over entire length of cells. Collapsed outer walls reflecting many small, underlying pits. Locally, patches with less pronounced pattern.

Specimens Examined:
ECUADOR: E. Asplund 9304 (G); Holguer Lugo S. 4824 (AAU); J. Jaramillo & F. Coello 3218 (AAU).

2.3. Section Hydristyles A. DC.

Plate 10d–k

The section was established by A. De Candolle in 1859 and was retained as such by subsequent monographers (Warburg, 1894; Irmscher, 1925). The three species recognized by Irmscher in 1925 have been increased to about 10 in subsequent years, including the transfer of two species from section Ruizo-
pavonia. The section deviates from related Andean sections by
the presence of five unequal petals and multifid styles in the fe-
male flower. The species are semishrubs and occur in Bolivia, 
Colombia, Ecuador, and Peru.

**Type Species.—** Begonia bridgesii A. DC. (Plate 10f).

**Seed Structure:** Seeds ellipsoid, 440–480 μm in length, 
205–235 μm in width, mean 460 μm × 215 μm, length:width 
ratio 2.1. Collar cells 120–195 μm in length, mean 150 μm, 
number in seed circumference about 13. Ratio of collar-cell 
length to seed length 3.1. Longitudinal anticlinal walls of collar 
straight, those of other testa cells more irregularly curved, 
sometimes locally undulated. Testa cells somewhat elongated. 
Opeculum nipple- to flat-nipple-shaped.

**Seed Micromorphology:** Anticlinal boundaries flat. Cuticu-
lar pattern short linear; cuticle locally with patches of thin, 
somewhat dense linear to undulated striae.

**Specimen Examined:**
aff. B. bridgesii, BOLIVIA: Dereims s.n. (P).

**Other Species Observed (Plate 10d,e,g–k).—** Seed Struc-
ture and Micromorphology: The seeds of the other species 
observed agree with those of B. bridgesii in the cellular pattern 
and in the short linear cuticular striae. They differ in shape, 
seed size, and the thickness and undulation of the anticlinal 
walls. The smaller seeds are found in B. juntasensis Kuntze and 
B. subcaudata Rusby ex L.B. Smith & B.G. Schubert, with 
mean seed sizes of 340 μm × 175 μm and 380 μm × 185 μm, 
respectively. The longest ones are found in B. santarosensis 
Kuntze, with a mean size of 630 μm × 205 μm and a length:
width ratio of 3.1. The anticlinal walls vary from weak-
ly undulated in B. subcaudata; to undulated in B. andina 
Rusby, B. juntasensis, and B. santarosensis; to strongly undulated 
in B. unduavensis Rusby.

Thicker anticlinal walls with sunken anticlinals are found loc-
ally in B. juntasensis and B. unduavensis (G. Mandon 1089). 
More distinct pockets are found in B. juntasensis and B. santar-
rosensis.

**Specimens Examined:**
B. andina, BOLIVIA: R.S. Williams 1566 (K).
B. juntasensis, PERU: H.E. Moore Jr., Salazar, & Smith 8601 
(US).
B. santarosensis, BOLIVIA: s.n. (P).
B. subcaudata, BOLIVIA: St.G. Beck 9253 (US).
B. unduavensis, BOLIVIA: St.G. Beck 4691 (US); G. Mandon 
1089 (K).

**2.4. Section Warburgina O. Kuntze**

**PLATE 10f**

The section was named by O. Kuntze in 1893 on the basis of 
its then newly described species, B. comata. The section is 
monotypic and is restricted to Bolivia. The characters of the sec-

tion agree to a large extent with those of section Hydristyles 
and also with those of sections Huszia (=Eupetalum) and 
Ruizopavonia. Section Warburgina differs from these sections 
by having pauciflorous inflorescences enveloped by numerous 
bracts.

**Type Species.—** Begonia comata Kuntze (Plate 10f).

**Seed Structure:** Seeds ellipsoid to narrowly ellipsoid, 
365–435 μm in length, 170–185 μm in width, mean 420 μm × 
175 μm, length:width ratio 2.2. Collar cells elongated, some-
times divided, 125–200 μm in length, mean 175 μm, number in 
seed circumference about 10. Ratio of collar-cell length to seed 
length 2.4.

Anticlinal walls of collar straight or almost straight, those of 
other testa cells strongly undulated, with pockets at bases of 
curves. Testa cells somewhat elongated. Opeculum nipple-
shaped.

**Seed Micromorphology:** Anticlinal boundaries sunken, 
those of collar cells strongly undulated. Cuticular pattern short 
linear, mostly shortly undulated toward anticlinals. Periclinal 
walls thin, locally reflecting underlying pits.

**Specimen Examined:**
B. comata, BOLIVIA: St.G. Beck 12651 (US).

**2.5. Section Gobenia A. DC.**

**PLATE 11a–d,f,g**

The section was established by A. De Candolle in 1859 and 
was retained as such by subsequent monographers. It includes 
about 15 species and occurs in the northern Andes, mainly Ec-
uador. Some of the distinguishing characteristics of the section 
are united filaments with sessile anthers and pistillate flowers 
that have extremely small styles with thick, auriculate stigmata. 
Fruits have three to four ribs or only one wing and are subten-
dent by persistent bracteoles. The leaves are usually peltate. 
The species are climbing herbs or semishrubs.

**Type Species.—** Begonia maurandiae A. DC. (Plate 11a,d).

**Seed Structure:** Seeds ellipsoid, irregular in shape, often 
oblquely flattened at chalazal side, 500–610 μm in length, 
225–285 μm in width, mean 555 μm × 250 μm, length:width 
ratio 2.2. Collar cells 125–290 μm in length, mean 185 μm, 
number in seed circumference about 15. Ratio of collar-cell 
length to seed length 3.0. Anticlinal walls of testa cells straight, 
sometimes slightly curved. Testa cells at chalazal end deeper 
due to elevated anticlinal walls. Opeculum broadly nipple-
shaped, cells bordering collar elongated, forming distinct ring. 
Micropylar rim often oblique, hilum sunken.

**Seed Micromorphology:** Anticlinal boundaries always 
straight. Cuticular pattern with long linear striae, sometimes 
slightly undulated. Locally, patches with zigzag striae.

**Remarks:** Seeds of collection Ed. André 3315 (originally 
identified as B. hederaacea A. DC.) deviate from above-de-
scribed collection (W.H. Camp E 4974) in the following char-
acters: mean seed size 420 μm × 170 μm, length:width ratio 
2.5; number of collar cells in seed circumference about 11; tes-
ta cells with more pronounced anticlinal walls and locally 
sunken anticlinal boundaries.
Specimens Examined:

OTHER SPECIES OBSERVED (Plate 11b, c, f, g).—Begonia pululahuanana C. DC., B. secunda L.B. Smith & D.C. Wasshausen, B. sodiroi C. DC., and B. ynesiae L.B. Smith & D.C. Wasshausen closely resemble one another and agree with B. maurandiae (Camp E 4974) in general characters, including the large number of collar cells. The seeds are even more variable in shape, sometimes somewhat J-shaped and/or slightly distorted. Mean seed size is 545 μm × 215 μm in B. pululahuanana, 450 μm × 200 μm in B. secunda, 590 μm × 225 μm in B. sodiroi, and 560 μm × 220 μm in B. ynesiae. In the last species, the anticlinal walls are locally undulated.

Specimens Examined:
B. pululahuanana, ECUADOR: E.W. Davis 500 (US).
B. secunda, ECUADOR: A. Gentry & G. Shupp 26638 (MO).
B. ynesiae, ECUADOR: Ynes Mexia 7706 (K, isotype).

2.6. Section Meionanthera A. DC.

PLATE 11e, h

The section was established by A. De Candolle in 1859 and has remained monotypic, with its only species B. holtonis A. DC. The section is characterized by very small, subglobose anthers on long slender filaments, elongate tepals of the pistillate flowers, ovaries with entire placentas, and three-celled fruits with one large wing and two highly vestigial wings. The species is restricted to Colombia. The seeds are not very characteristic and resemble the ordinary type of begonia seed.

Seed Structure and Micromorphology: The seeds of B. holtonis var. holtonis are ellipsoidal, with a mean size of 360 μm × 195 μm. The testa cells are polygonal, with straight or very slightly undulated anticlinal walls, and the operculum is nipple-shaped. The cuticular ornamentation is a fine, dense pattern of short linear or undulated striae. Locally, there are patches with a labyrinth-like structure.

Specimens Examined:
B. holtonis var. holtonis, COLOMBIA: F.A. Barkley c.s. 66 (US);
Holton 725 (G, isotype); J.L. Luteyn c.s. 10395 (MO); Uribe Uribe 3878 (US).

2.7. Sections Lepisia (Klotzsch) A. DC. and Tittelbachia (Klotzsch) A. DC.

PLATE 11j–n

The species of the small sections Lepisia and Tittelbachia resemble each other in several floral characters and in outer appearance.

TYPE SPECIES.—Begonia foliosa H.B.K. var. foliosa, type species of section Lepisia; B. fuchioides Hooker var. fuchioides, type species of section Tittelbachia.

Seed Structure and Micromorphology: The seeds of the two type species resemble the ordinary type of begonia seed. They are mostly medium-sized, 355 μm × 180 μm and 490 μm × 240 μm, respectively, with distinctly elongated collar cells, variable undulation of the anticlinal testa cells, flat anticlinal boundaries, and a fine, dense cuticular pattern of mainly short linear or undulated striae.

The seeds of the different varieties of B. foliosa are rather polymorphic. The seeds of B. foliosa var. putzeysiana (A. DC.) Smith & Schubert are relatively long, with a mean size of 585 μm × 230 μm and a length:width ratio of 2.5. The seeds of B. foliosa var. rotundata Smith & Schubert have a very dense cuticle that somewhat obscures the anticlinal walls. The synonymy of B. poeppigiana A. DC. with B. foliosa var. australis Smith & Schubert is sustained by seed micromorphology.

Specimens Examined:
B. foliosa var. australis, ECUADOR: Jameson s.n. (B), PERU: Matthias & Taylor 5905 (MO).
B. foliosa var. foliosa, COLOMBIA: Oscar Haught 6159 (K); PERU: Herb. Splitgerberianum (L).
B. foliosa var. putzeysiana, COLOMBIA: Killip & A.C. Smith 19817, 20090 (US).
B. foliosa var. rotundata, COLOMBIA: McDougal & Roldan 3540 (US).
B. fuchioides var. miniata A. DC., COLOMBIA: Uribe Uribe 5005 (US).

OTHER SPECIES OBSERVED.—The seeds of B. microphylla A. DC. are about 550 μm in length and differ from the species described above by having a more irregular seed shape, a broadly nipple-shaped operculum, and testa cells with more elevated anticlinal walls, causing a more shallow appearance. The seeds resemble those of species of section Gobenia. The collection P.E. Berry 3291 is more or less intermediate between the collection F.J. Breteler 4643 and B. foliosa collections.

Specimens Examined:
B. microphylla var. microphylla, VENEZUELA: P.E. Berry 3291 (MO); F.J. Breteler 4643 (MO); L. Ruiz-Teran 393 (US).

2.8. Section Eupetalum (Lindley ex Klotzsch) A. DC., Including the Former Section Huszia (Klotzsch) A. DC.

PLATES 12, 13a–e

Section Eupetalum is mainly Andean, with species known from Ecuador and Peru. The type species, B. geraniifolia Hooker, has several synonyms.

Smith and Wasshausen (1979, 1986) included the species of section Huszia in section Eupetalum. The species of former section Huszia occur in Bolivia, Peru, and Colombia, occasionally extending into Venezuela or occurring in Mexico.

The species of the two sections as formerly recognized resemble each other quite closely and differ mainly in stem length.
The seeds of all species examined resemble the ordinary type of begonia seed. Although several species locally show crow’s-foot-like cuticular striae, the seeds lack distinct features characteristic at the sectional level. Moreover, the seeds show some variation in size, shape of operculum, thickness of anticlinal walls, and density of the cuticular pattern.

FORMER SECTION Huszia.—Seed Structure and Micro-morphology: The seeds of the former type species, B. octopetala l’Héritier, have a mean size of 340 μm × 180 μm and a length:width ratio of 1.9. The seeds of B. erythrocarpa A. DC., B. pastoensis A. DC., and B. pleiopetala A. DC. resemble those of B. octopetala in size, testal pattern, and in the very dense cuticular pattern, which consists of short zigzag and crow’s-foot-like striae. The synonymy of B. macbrideana Irmscher with B. erythrocarpa as stated by Smith and Wasshausen (1984) is not substantiated by the seeds examined in this study. Begonia macbrideana has a different cuticular pattern and further differs by having an obtuse operculum, a larger number of collar and testa cells, and straight anticlinal. It has the biggest seeds observed in the former section Huszia, with a mean size of 455 μm × 300 μm and a length:width ratio of 1.5.

Remarks: The seeds of the three collections of the Mexican species B. monophylla Pavon ex A. DC. studied (all collected as B. unifolia Rose ex Trelaeze) closely resemble each other and differ from the seeds of all other Eupetalum species by having a broad, nipple-shaped operculum, broader anticlinal walls, and a coarser cuticular pattern of mainly zigzag striae.

Specimens Examined:
B. cinnabarina, BOLIVIA: R. de Michel 16 (US).
B. erythrocarpa, PERU: Wasshausen & Salas 1194 (K).
B. hydrophyloides, COLOMBIA: M. Idrobo & Evans Schultes 560 (US).
B. macbrideana, PERU: Weberbauer 2011 (B).
B. macro A. DC. aff., VENEZUELA: Steyermark & Rabe 97300 (B).
B. monophylla, MEXICO: C.G. Pringle s.n. (L, PRE); J.N. Rose c.s. 9367 (P).
B. octopetala, PERU: L. Holm-Nielsen c.s. 3404 (MO); A. Lopez c.s. 2709 (US); O. Tovar 3600 (US).
B. pastoensis, COLOMBIA: F.C. Lehman 5404 (B); J. Triana s.n. (P).
B. pearcei, CULTIVATED: van Veldhuizen 580 (WAG).
B. pleiopetala, PERU: Buchten 653 (B); Weberbauer 6026 (B).
B. tumbezensis, PERU: Weberbauer 7685A (B).
B. veitchii J.D. Hooker, PERU: A. Miguel Bang 1862 (B). CULTIVATED: van Veldhuizen 1108 (WAG).

SECTION Eupetalum.—Seed Structure and Micro-morphology: The seeds of the three collections of the type species, B. geraniifolia, closely resemble one another. The mean seed size is 340 μm × 195 μm, with a length:width ratio of 1.7. They resemble the seeds of the former section Huszia species B. cinnabarina Hooker, B. hydrophyloides Smith & Schubert, B. pearcei Hooker, B. serotina A. DC., and B. tumbezensis Irmscher in general characters, their length:width ratio, and their more granular cuticular ornamentation.

The seeds of the remaining species studied agree in the dense cuticular pattern but show some variation in other characters.

Specimens Examined:
B. geraniifolia, PERU: Dowbey s.n. (P); A. Lourteig 3117 (K); Sela 259 (B).
B. novogranatae A. DC., COLOMBIA: M.T. Dawe 272 (K, as B. inanis Irmscher, isotype); P.J. Grubb, Curry, & Fernandez-Perez 628 (K).

2.9. Section Apteroid C. DC.

PLATE 13de

This monotypic section differs from the other sections by having globose, wingless fruits; it is endemic to Ecuador.

TYPE SPECIES.—Begonia exalata C. DC.

Seed Structure and Micro-morphology: The seeds of B. exalata conform to the ordinary type of begonia seed. The mean seed size is 335 μm × 210 μm, with a length:width ratio of 1.6. The anticlinal walls are straight, slightly curved, or obscured undulated. The operculum is nipple-shaped. The cuticular pattern is quite characteristic, consisting of very dense, mainly short zigzag striae almost without a distinct delimitation at the anticlinals, resulting in a woolly appearance of the seed surface.

The seeds resemble those of B. pastoensis of section Eupetalum (Huszia).

Specimen Examined:
B. exalata, ECUADOR: Södéro 597 (US, isotype).

2.10. Section Barya (Klotzsch) A. DC.

PLATE 13f–j

Striking characters in section Barya are the presence of erect, lanceolate tepals in both stamine and pistillate flowers and unequal stamens united into an elongated column. Begonia monadelpha Ruiz & Pavon ex A. DC. and B. soror Irmscher occur in Peru; B. boliviensis A. DC. is known from Bolivia and Argentina.

TYPE SPECIES.—Begonia monadelpha (Plate 13h).

Seed Structure: Seeds ellipsoid to narrowly ellipsoid, somewhat irregular in shape. Length 450–555 μm, width 210–240 μm, mean 510 μm × 225 μm, length:width ratio 2.7. Collar cells elongated, 145–250 μm in length, mean 200 μm, number in seed circumference about 13. Ratio of collar-cell length to seed length 1:2.6. Longitudinal anticlinal walls of collar straight, those of other testa cells straight, curved, or slightly undulated, with pockets. Operculum obtuse to broadly nipple-shaped.
Seed Micromorphology: Anticlinal boundaries straight or locally sunken. Cuticular pattern with linear or short undulated striae.

Remarks: The seeds of collection Barbour 3993 differ in several respects from the above-described collection Weberbauer 6714, being ellipsoid and somewhat smaller, with a mean seed size of 465 μm × 240 μm, a length:width ratio of 1.9, and having thicker, shorter anticlinals.

Specimens Examined:
B. monadelpha, PERU: P. Barbour 3993 (MO); A. Weberbauer 6714 (US).

Other Species Observed (Plate 13f,g,j).—Seed Structure and Micromorphology: The seeds of B. soror quite closely resemble those of B. monadelpha collected by Weberbauer. They have a sunken micropyle and less undulated anticlinal walls.

The seeds of B. boliviensis A. DC. differ from the above-mentioned species and more resemble the ordinary begonia seed type. They have a mean seed size of 355 μm × 230 μm, with a length:width ratio of 1.5. The collar cells vary in length from 85 μm to 165 μm, with a mean of 125 μm. The ratio of collar-cell length to seed length is 1:2.8. The operculum is nipple-shaped. The cuticular pattern is short linear to short undulated striae.

Specimens Examined:
B. soror, PERU: J.J. Wurdack 1627 (US).

3. Sections Occurring Both in Brazilian and in Andean Regions

Only two sections have a distribution both from Brazil or Argentina and from the Andean countries.

3.1. Section Pilderia A. DC.
PLATE 13k,n

Klotzsch's genus Pilderia was reduced to sectional level by A. De Candolle (1859). The section is characterized by staminate flowers with two to four tepals and pistillate flowers with five persistent tepals and undivided placentas. The plants are herbs or semishrubs with a yellowish pubescence. The section is probably monotypic. Begonia buddleifolia A. DC. has a distribution from Brazil and Peru to Venezuela.

Type Species.—Begonia buddleifolia A. DC. (Plate 13k,n).

Seed Micromorphology: Anticlinal boundaries flat, sometimes locally sunken. Cuticular ornamentation consisting of zigzag striae of various length.

Specimens Examined:

3.2. Section Australes Smith & Schubert
PLATE 13l,m,o

The section was established by Smith and Schubert in 1941 and comprises herbaceous or almost herbaceous species with a small tuber at the stem base. The staminate and pistillate flowers have four and five tepals, respectively. The three styles are deeply two-divided on the back and are more or less wavy on the front. The section contains four species, all occurring in Argentina. Begonia micranthera, with several varieties, also extends to Bolivia and Peru.

No seeds were available of B. parodiana L.B. Smith & B.G. Schubert and B. sleumeri L.B. Smith & B.G. Schubert.

Type Species.—Begonia micranthera Grisebach (Plate 13m,o).

Seed Structure: Seeds elliptic. Mean seed size 405 μm × 240 μm in B. micranthera var. micranthera, 420 μm × 230 μm in B. micranthera var. foliosa L.B. Smith & B.G. Schubert, and 340 μm × 210 μm in B. micranthera var. fimbriata L.B. Smith & B.G. Schubert. Length:width ratios 1.7, 1.8, and 1.6, respectively. Relatively many testa cells, those adjacent to collar somewhat elongated, chalazal ones polygonal. Anticlinal walls straight, slightly curved, or slightly undulated. Operculum cone-shaped.

Seed Micromorphology: Anticlinal boundaries flat, locally sunken in B. micranthera var. fimbriata. Cuticle with short, undulated striae and with slight double structure in B. micranthera var. fimbriata and var. foliosa.

Specimens Examined:
B. micranthera var. fimbriata, ARGENTINA: J. West 8413 (MO, isotype).
B. micranthera var. foliosa, ARGENTINA: S. Venturi 3457 (US); J. West 6216 (MO).

Other Species Observed (Plate 13l).—The seeds of B. tafiensis Lillo closely resemble those of B. micranthera var. foliosa in size and morphological characters.

Specimen Examined:
B. tafiensis, ARGENTINA: S. Venturi 3093 (US).

4. Sections Mainly Confined to the Central American, Mexican, and Caribbean Regions

Of the eight sections confined to Middle America, six could be studied for their seed structure. Of these only one, Urniformia, shows a characteristic seed structure that distinguishes
it from all other Neotropical sections. No seeds for study were available of the monotypic sections Cylindrobegonia and Parietooplacentalia.

4.1. Section Urniformia Houghton ex Ziesenhenne

**PLATE 14a,b**

This section was drafted by Houghton in 1924 but wasn’t published by Ziesenhenne until 1974. The section is monotypic and is restricted to Costa Rica, Guatemala, and Panama. The section is characterized by a one-celled ovary and a capsule with three long, hollow, fleshy horns.

**TYPE SPECIES.**—*Begonia heydei* C. DC. (Plate 14a,b).

**Seed Structure:** Seeds ellipsoid, 540–620 μm in length, 255–295 μm in width, mean 585 μm 280 μm, length:width ratio 2.1. Collar cells 165–244 μm in length, mean 205 μm, number in seed circumference about 11. Ratio of collar-cell length to seed length 1:2.9. Testa cells polygonal, sometimes somewhat elongated toward collar. Anticlinal walls curved or slightly undulated. Operculum narrowly, nipple-shaped.

**Seed Micromorphology:** Anticlinal boundaries flat. Cuticle smooth, without ornamentation; locally, striae on anticlinal walls of operculum.

**Specimens Examined:**

- *B. heydei*, COSTA RICA: Haber & Bello 7645 (MO); R.A. Ocampo 1323 (CR); Stone & Stone 2712 (US).

4.2. Section Gireoudia (Klotzsch) A. DC.

**PLATES 14c–n, 15a–c**

*Gireoudia* was described by Klotzsch in 1854 as a genus. It was reduced to a section by A. De Candolle in 1859. Later, *Gireoudia* was considered to be a subsection of section Magnusia along with subsections Rachia and Psathuron. On the basis of priority, *Gireoudia* is now treated as a section including Magnusia and Psathuron. Rachia is now included in section Knesebeckia. Section Gireoudia includes the monotypic section Aurifurria Ziesenhenne by the synonymy of *B. bakeri* C. DC. with *B. cardiocarpa* Liebmann (Burt-Utley, 1985). We accept the proposal by Burt-Utley (1985) to select *B. plebeja* Liebmann as lectotype of section Gireoudia above the more arbitrarily chosen species *B. involucrata* Liebmann (Baranov & Barkley, 1974).

The Central American and Mexican species of the section have been revised by Burt-Utley (1985, 1990). The section is characterized by staminate and pistillate flowers with two tepals and pistillate flowers with two-parted placentas. The plants are rhizomatous perennials or suffrutescent herbs. The section comprises over 60 species, most of which are endemic and restricted to Mexico and Central America. Four species are reported from Colombia, Venezuela, and Guyana.

**TYPE SPECIES.**—*Begonia plebeja* (Plate 14c,f).

**Seed Structure:** Seeds ellipsoid. Mean seed size 365 μm × 185 μm, length:width ratio 2.0. Testa cells polygonal or more elongated. Anticlinal walls slightly curved. Operculum nipplete broadly, nipple-shaped.

**Seed Micromorphology:** Anticlinal boundaries flat. Cuticular pattern mainly consisting of short undulated striae. Locally, patches without distinct ornamentation.

**Specimens Examined:**

- *B. plebeja*, COSTA RICA: John Taylor 17305 (US).

**OTHER SPECIES OBSERVED** (Plates 14d,e,g–n, 15a–c).—The seeds of all species observed by us conform to the ordinary seed type. Seeds vary to some extent in size, number of testa cells, and in micromorphology.

**Seed Structure:** Seed length varies from 310 μm in *B. jenmannii* Tutin to 445 μm in *B. crassicaulis* Lindley and *B. urophylla* W.J. Hooker. The anticlinal walls are mostly straight, slightly curved, slightly undulated (*B. barkeri* Knowles & Westcott, *B. multiflora* Liebmann, *B. urophylla*), or undulated (*B. sartorii* Liebmann).

**Seed Micromorphology:** The anticlinal boundaries are always flat. Cuticular ornamentation in most species is mainly granular to short zigzag, as in *B. sericoneura* Liebmann, or short undulated, as in *B. nelumbifolia* Schlechtendal & Chaminiso. The cuticular pattern is fine and very dense, as in *B. cardiocarpa*.

**Specimens Examined:**

- *B. barkeri*, MEXICO: Bourgeois 2968 (L); Ch.L. Smith 690 (US).
- *B. conchifolia* Dietrich var. conchifolia, PANAMA: Wilbur 24349 (CR).
- *B. fuscata* Liebmann, MEXICO: Botteri & Sumichrast 1631 (P).
- *B. heracleifolia* Schlechtendal & Chaminiso var. heracleifolia, MEXICO: Bourgeois 1583 (P).
- *B. involucrata*, COSTA RICA: P.C. Standley 34241 (US); Stanley & Valerio 48137 (US).
- *B. jenmannii*, BRITISH GUIANA (=Guyana): B. Maguire & Fanshawe 23081 (U).
- *B. multiflora*, COSTA RICA: cult., van Veldhuizen 661 (WAG).
- *B. nelumbifolia*, CULTIVATED: Gent, B.K. Boom 16850 (L).
- *B. sartorii*, MEXICO: Bourgeois 2100 (L).
- *B. sericoneura*, HONDURAS: cult., van Veldhuizen 392 (WAG).
- *B. squarrosa* Liebmann, MEXICO: cult., van Veldhuizen 623 (WAG).
- *B. urophylla*, COSTA RICA: cult., van Veldhuizen 655 (WAG).

4.3. Section Hexaptera Ziesenhenne

**PLATE 15d,e**

In 1974 Ziesenhenne established this monotypic section to accommodate *B. oaxacana*, formerly belonging to section *Knesebeckia*. The section is characterized by the presence of erect
fruits with six small wings. This character, however, is not always present in this variable species. The species occurs in Panama, Costa Rica, Nicaragua, Guatemala, and southern Mexico.

The seeds of *B. oaxacana* differ to some extent from the ordinary type of begonia seed.

**TYPE SPECIES.**—*Begonia oaxacana* A. DC. var. oaxacana (Plate 15d,e).

**Seed Structure:** Seeds ellipsoid. Mean seed size 480 µm × 255 µm, length : width ratio 1.9. Testa cells more or less polygonal, with straight, curved, or sometimes slightly undulated anticlinal walls; anticlinal walls thickened. Operculum nipple- to broadly nipple-shaped.

**Seed Micromorphology:** Anticlinal boundaries always flat. Cuticular structure variable, from mostly faint linear, to short linear in collection McVaugh 10266, to smooth in collection Davidse et al. 26139.

**Remarks:** The seeds of collection McWilliams & Molina 42675 are comparable in size and shape; however, they differ in having a greater number of collar and testa cells, mainly straight anticlinal walls, and a more distinct cuticular pattern of short zigzag striae.

The seeds of collection McVaugh 10266 strongly resemble those of *B. udysylvestris* C. DC., a species placed in section *Ruizopavonia* by Barkley and Golding (1974). The seeds of collection Davidse et al. 26139 resemble those of *B. heydei* (section *Urniformia*) in shape, the smooth cuticle, and the thicker anticlinal walls.

**Specimens Examined:**

4.4. **Section Dissepegonia** Ziesenhenne

**Plate 15f,g**

This section was established by Ziesenhenne in 1948 on the basis of the newly described species *B. cavum* Ziesenhenne, found in a small cave in Oaxaca, Mexico. The section closely resembles section *Knesebeckia* but can be distinguished by the presence of placenta affixed to the inner walls of the locules. Later the section was extended with *B. palmeri* S. Watson (Barkley and Golding, 1974).

**SPECIES OBSERVED.**—Unfortunately no seeds were available of *B. cavum*. The seeds of *B. palmeri* are not characteristic and resemble the ordinary type of begonia seed.

**Seed Structure and Micromorphology:** Seeds of *B. palmeri* have a mean seed size of 355 µm × 205 µm, with a length : width ratio of 1.7. The testa cells are polygonal, with straight or curved anticlinal walls. The operculum is nipple- to broadly nipple-shaped. The cuticular structure is faint-granular, with more prominent short linear or short undulated striae.

**Specimen Examined:**

*B. palmeri*, MEXICO: Ynes Mexia 219 (MO).

4.5. **Section Podandra** A. DC.

**Plate 15h,j**

The section is characterized by staminate and pistillate flowers with four and five tepals, respectively, and filaments united into a column. The section comprises the type species *B. decandra* Pavon ex A. DC. from Puerto Rico and Mexico. The inclusion of a second species, *B. trichosepala* C. DC. from Guatemala (Barkley and Golding, 1974), is disputed (Doorenbos et al., 1998). No seeds of the latter species were available.

**TYPE SPECIES.**—*Begonia decandra*.

**Seed Structure:** Seeds ellipsoid, mean size 370 µm × 180 µm, length : width ratio 2.1. Collar cells distinctly elongated, other testa cells rectangular. Anticlinal walls of collar and testa cells varying between collections: strongly undulated in *Krug & Urban 1121*, undulated to weakly so in *Hoffmann 876*, and weakly undulated to almost straight in *Sintenis 5341*. Operculum nipple-shaped.

**Seed Micromorphology:** Anticlinal boundaries varying among collections: mostly sunken in *Krug & Urban 1121*, locally sunken in *Hoffmann 876*, and almost always flat in *Sintenis 5341*. Cuticular pattern consisting of short linear and short undulated striae.

**Specimens Examined:**

*B. decandra*, PUERTO RICO: O. Hoffmann 876 (B); *Krug & Urban 1121* (L); P. *Sintenis 5341* (P).

4.6. **Section Weilbachia** (Klotzsch & Oersted) A. DC.

**Plate 15k–o**

*Weilbachia* was originally described as a genus but was reduced to a section by A. De Candolle (1859). The section probably includes section *Liebmanna* Ziesenhenne, as it is similar to, if not indistinguishable from, section *Weilbachia* (Burt-Utley, 1985). The section is characterized by staminate flowers with two or four tepals and by pistillate flowers with two or three tepals and two-celled ovaries with two or three styles and two-parted placentas. The section is restricted to Central America and Mexico and comprises about 20 species (Burt-Utley, 1985).

**TYPE SPECIES.**—*Begonia ludicra* A. DC. (syn. *B. liebmannii* A. DC.). The original type species was described by Klotzsch as *Weilbachia reptans*, which was renamed *Begonia liebmannii* by A. De Candolle in 1864.

**SPECIES OBSERVED** (Plate 15k–o).—**Seed Structure:** Seeds ellipsoid, varying in size from 320 µm × 195 µm in *B. aridicallis* Ziesenhenne to 415 µm × 215 µm in *B. pulchulata* Liebmann, with length : width ratios of 1.6 and 1.9, respectively. Testa cells irregularly polygonal. Anticlinal walls undulated in most species but straight to curved in *B. purpurs* Houghton ex Ziesenhenne. Operculum nipple-shaped.
Seed Micromorphology: Anticlinal boundaries always flat. Cuticular pattern short undulated, short linear, or granular. Outer pericellular wall sometimes rather thin, almost without cuticular ornamentation, and reflecting underlying pits, as in *B. imperialis* Lemaire.

Specimens Examined:
- *B. imperialis var. imperialis*, MEXICO: DTH 5397 (L).

5. Section Mainly Occurring in Both Andean and Middle American Regions

Only one section has a distribution more distinctly restricted to the Andes and Central America and Mexico.

5.1. Section *Ruizopavonia* A. DC.

Plates 16, 17a,b

The section was established by A. De Candolle in 1859. Irmscher (1949) discussed the delimitation of the section. *Begonia corredorana* C. DC. and *B. thiemei* C. DC., affiliated to this section by Barkley and Golding (1974), were included in section *Gireoudia* by Burt-Utley (1985).

Most species of the section have only two tepals in the staminate and pistillate flowers, but in some species there are three tepals in the staminate flowers and up to four tepals in the pistillate flowers. The connective of the stamens is a little extended. The styles are deeply two-parted and are sometimes divided again. The plants are suffrutescent, shrubby, or climbing, predominantly with pinnately veined leaves, and with small deciduous bracteoles. The section comprises about 35 species, mostly from the Andes, but eight species are reported from Central America and/or Mexico.

Type Species.—*Begonia alnifolia* A. DC. (Plate 16a.b).

Seed Structure: Seeds ellipsoid, resembling ordinary *Begonia* seed type. Mean seed size of collection *Mocquereys 1219*: 325 µm × 195 µm, length: width ratio 1.7. Collar cells elongated, other testa cells relatively few in number. Anticlinal walls of testa cells thin and straight to curved. Operculum nipple-shaped.

Seed Micromorphology: Anticlinal boundaries flat. Cuticular pattern linear or undulated. Locally, patches without a smooth or fine structure.

Remarks: Seeds of *B. aff. alnifolia* collection *A.C. Smith 3169* deviate by having somewhat larger seeds, undulated anticlinals, and a less dense cuticular pattern with underlying pits.

Specimens Examined:

Species Comparable to *B. alnifolia* (Plate 16c–h,k,l).—Seeds of most of the species observed of section *Ruizopavonia* resemble one another in their relatively small size, curved undulated anticlinals, and in their fine cuticular structure, consisting of linear or undulated striae.

Seed Structure and Micromorphology: Mean seed length varying from 225 µm in *B. corredorana* C. DC., to 255 µm in *B. cooperi* C. DC., to 415 µm in *B. carpinifolia* Liebm. Length: width ratio ranging from 1.4 in *B. peruviana* A. DC. to 2.1 in *B. convallariodora* C. DC. *Begonia carpinifolia* seeds with relatively many testa cells. Seeds of *B. bracteosa* A. DC. resembling those of several Andean species in section *Begonia*, such as *B. cyatophora* Poeppig & Endl. Anticlinal walls varying from almost straight, to curved (*B. peruviana*), to distinctly undulated (*B. seemanniana* A. DC.). Compared with other species resembling *B. alnifolia*, seeds of *B. bracteosa* with thicker, curved to undulated anticlinal walls, locally with sunken anticlinal boundaries and coarser cuticular pattern of short linear or short undulated striae.

Specimens Examined:
- *B. bracteosa*, PERU: Ellenberg 815 (U).
- *B. carpinifolia*, COSTA RICA: Kappelle & Monge 3635 (CR).
- *B. consobrina* Irmscher, COLOMBIA: Schultes & Villarreal 7704 (K).
- *B. convallariodora*, COSTA RICA: Scott Hoover 582 (MO). PANAMA: Seibert 207 (K).
- *B. cooperi*, CULTIVATED: *van Veldhuizen 396* (WAG).
- *B. peruviana*, PERU: Sandeman 4378 (K).

Species Differing from *B. alnifolia* (Plates 16j,m,o. 17a,b).—The seeds of four species examined differ distinctly from those described above.

*Begonia udlysylvestris* C. DC.: Mean seed size 545 µm × 295 µm, length: width ratio 1.8. Anticlinal boundaries flat, with or without faint cuticular ornamentation. Outer pericellular walls of testa cells often with central field of short undulated striae and longer linear striae radiating toward anticlinal walls.

*Begonia suprafasciigata* Irmscher: Mean seed size 435 µm × 190 µm, length: width ratio 2.3. Testa cells elongated, in regular rows in continuation of collar cells. Anticlinal walls of testa cells distinctly undulated.

*Begonia cuatrecasiana* Smith & Schubert: Seeds ellipsoid to narrowly ellipsoid, somewhat varying in shape and dimensions. Operculum obtuse, chalazal end extended. Mean seed size 385 µm × 150 µm, with length: width ratio of 2.6. Anticlinal walls curved to undulated, locally with pockets. Anticlinal
boundaries flat, crosshatched. Seeds of *B. cuatrecasiana* show tendency to scobiformy, as seen more extremely in section *Rossmannia* (see Smith and Schubert, 1946).

*Begonia estrellensis* C. DC.: Seeds narrowly ellipsoid, with obtuse operculum and extended chalazal end. Mean seed size 625 μm × 170 μm, length:width ratio 3.7. Testa cells elongated. Anticlinal walls elevated and slightly undulated, with many pockets along walls. Cuticular pattern mainly long linear striae. Seeds of collection Lieneser 1023 somewhat smaller and more tapering toward chalazal end.

Remarks: The seeds of *B. estrellensis* resemble those of *B. santarosensis* of section *Hydristyles*. The seeds of *B. udisylvestris* resemble those of *B. oaxacana* of section *Hexaptera*.

Specimens Examined:
B. *cuatrecasiana*, COLOMBIA: Forrero-Jaramillo 2403 (COL).

PANAMA: Lieneser 1023 (L).
B. *suprafustigiata*, PERU: Weberbauer 7907 (B, holotype).
B. *udisylvestris*, COSTA RICA: Burger & Stolze 5250 (CR).

6. Sections with a Wide Neotropical Distribution

The four sections discussed below comprise species distributed over a wide area, ranging from Brazil to Mexico. Two sections, *Begonia* and *Knesebeckia*, also have species in Asia.

6.1. Section *Doratometra* (Klotzsch) A. DC.

PLATE 17c–m

The section is characterized in part by three two-parted styles with linear branches, undivided placentas, and palmately veined leaves. The species are self-fertilizing herbs. The section comprises about 12 species. Most species have a restricted distribution; *B. filipes* Bentham, *B. hirtella* Link, *B. humilis* Dryander, and *B. semiouata* Liebmann have a wider distribution in Central and South America. *Begonia hirtella* has been introduced and naturalized in, among other places, South Africa, Java, and Sri Lanka.

Type Species.—*Begonia wallichiana* Lehman (Plate 17d,g).

Seed Structure: Seeds elliptic, 315–365 μm in length, 185–205 μm in width, mean 340 μm × 195 μm. Length:width ratio 1.7. Collar cells relatively short, with mean length of 100 μm. Testa cells isodiametric, anticlinal walls rather thick, straight or curved or somewhat undulated. Operculum nipple-shaped.

Seed Micromorphology: Anticlinal boundaries flat. Cuticular pattern dense, consisting of mainly granular ornamentation.

Specimens Examined:

Other Species Observed (Plate 17c,e,f,h–m).—The seeds of species of this section show some variation in size and micromorphology; the seeds of *B. prieurii* A. DC. and *B. steyermarkii* Smith & Schubert in particular are quite characteristic.

Seed Structure and Micromorphology: The seeds of *B. filipes*, *B. humilis*, and *B. semiouata* are relatively small (e.g., 235 μm in *B. filipes*), and the anticlinal walls are thinner than in the type species; however, they agree with *B. wallichiana* in general morphology and in the granular cuticular ornamentation. The seeds of *B. tonduzii* C. DC. also are shorter than 300 μm and resemble the above-mentioned species in most characters; however, they deviate by having a sharp demarcation of the anticlinal walls.

The seeds of *B. hirsuta* Aublet and *B. hirtella* are about the same size as those of *B. wallichiana* and have a similar cuticular pattern, but they have more undulated anticlinals. *Begonia hirsuta* has seeds with thick anticlinal walls with obscured boundaries. Seeds of *B. hirtella* plants introduced to and escaped in Java and Sri Lanka more resemble seeds of *B. hirsuta*.

The seeds of *B. prieurii* and *B. steyermarkii* distinctly deviate from the above-mentioned species. The periclinal walls of both the testa and collar cells reflect the presence of more or less evenly distributed knobblies. The anticlinal walls are rather thick in *B. prieurii* and are very thick and distinctly undulated in *B. steyermarkii*. The cuticular pattern consists of short and long zigzag elevated striae. The seeds of the two Brazilian collections of *B. prieurii* are to some extent intermediate between the Guianan collections and *B. steyermarkii*. The seeds of *B. steyermarkii* resemble seeds of certain species of section *Caspara* in general shape and in testal pattern.

Specimens Examined:
B. *prieurii*, FRENCH GUIANA: Granville 2519 (US); C. Sastre 1698 (US), 1733 (U). BRAZIL: H.S. Irwin c.s. 48113 (US); T. Plowman c.s. 8243 (US).

6.2. Section *Begonia* Baranov & Barkley

PLATEs 18, 19

Baranov and Barkley (1972) named section *Begonia* on the basis of the rules and recommendations of the International Code of Botanical Nomenclature (ICBN). The section comprises parts of the former section *Begoniastrum* A. DC. The taxonomic delimitation of section *Begoniastrum* changed sev-
eral times. According to Baranov and Barkley (1972), section Begonia includes the former subsection Eubegonia Warburg and the sections Moschkwitizia (Klotzsch) A. DC. and Cyato
cemis (Klotzsch) A. DC., but Knesbeckia. reduced by Warburg (1894) to a subsection, is again a section in its own right. Section Begonia has no unique characters and is cir-
cumscribed by a combination of more general character states, such as staminate flowers with four (sometimes two) tepals and oblong to linear anthers that are longer than the fil-
aments and pistillate flowers with usually five (sometimes six) tepals and bipartite placentas. With about 75 species, it is the section with the largest number of species in the Neotropics, but according to Barkley and Golding (1974), it also in-
cludes about 12 Asian species.

Some groupings can be made on the basis of seed structure. The most distinct is the B. cucullata—B. fischeri group, the species of which mainly are found in Brazil, Argentina, Para-
guay, and Uruguay, although B. fischeri has a more widespread distribution.

Several species, often endemic, are present in the Caribbean region. The seeds of these species may resemble those of the section type, B. obliqua, or they may resemble the seeds of the more widespread B. guaduensis.

Begonia obliqua Group

Begonia obliqua LINNAEUS (Plate 18a,d).—Type species of section Begonia.

Seed Structure: Seeds elliptic, 295–420 μm in length, 180–205 μm in width, mean 360 μm × 195 μm, length:width ratio 1.8. Testa cells polygonal. Anticinal walls thin, straight, or almost straight, but undulated at bases. Operculum nipple-shaped.

Seed Micromorphology: Anticinal boundaries flat. Cuticular pattern faint, reflecting underlying pits; if present, pattern consisting of short zigzag striae.

Specimen Examined:

B. obliqua, MARTINIQUE: Duss 973 (US).

CARIBBEAN SPECIES OBSERVED (Plate 18b,c,e–h,k).—The seeds observed of species originating from the Caribbean region all belong to the ordinary begonia seed type and more or less resemble B. obliqua.

Seed Structure and Micromorphology: Begonia rotundi-
folia Lamarck and B. glandulifera Grisebach quite closely re-
semble B. obliqua in size, shape, and the thin anticinal and outer pericinal walls.

The seeds of B. odorata Willdenow and B. retusa Schulz re-
semble each other by the undulated anticinal walls of testa and operculum cells and are to some extent similar to those of the B. cucullata—B. fischeri group. The two species differ from each other somewhat in seed size and cuticular pattern.

The seeds of B. cubensis Hasskarl and of B. plumieri A. DC. var. barahonensis O.E. Schulz differ by having almost straight anticinal and more zigzag striae.

Specimens Examined:

B. cubensis, CUBA: J. Linden 1730 (GENT, as B. lindeniana A. DC., isotype). CULTIVATED: Ziesenhennne s.n.
B. glandulifera, TRINIDAD: Van Steenis 20304 (L).
B. aff. odorata, DOMINICA: J. Jérémie 1105 (P).
B. plumieri var. barahonensis, SANTO DOMINGO: Padre Miguel Fuertes 432 (L).
B. rotundifolia, WEST INDIES: Hortus Bot. Liège (cult.); Hortus Bot. Nancy (cult.).

MAINLY ANDEAN SPECIES OBSERVED (Plate 18j,l,m).—Seed Structure and Micromorphology: The seeds of B. guaduensis H.B.K., B. cyathophora (type species of former section Cya-
thocnemis), and B. portillana S. Watson strongly resemble those of B. odorata in shape, size, undulated anticinal walls, and in the mainly granular to short linear cuticular pattern. The two samples of B. cyathophora studied by us differ somewhat in the extent of undulation.

The seeds of B. alloperuviana A. DC. and B. barrigae Smith & Schubert also conform to the ordinary seed type and do not show special characters.

Specimens Examined:

B. alloperuviana, BOLIVIA: Wodell 4556 (P).
B. barrigae, COLOMBIA: cult., van Veldhuizen 872 (WAG).
B. cyathophora, PERU: Ellenberg 735 A (U); Y. Mexia 8128 (MO).
B. guaduensis, GUAYANA: Maas & Westra 3877 (U). PANAMA:
B. portillana, MEXICO: Dunn, Le Doux, & Torke 21820 (MO).

Begonia cucullata—Begonia fischeri Group

Begonia cucullata WILLDENOW (Plate 19a–d).—Seed Structure and Micromorphology: Among the specimens assigned to this species, three seed types are encountered: (1) narrowly ellipsoidal seeds having an obtuse micropylar end with sunken hilum and an extended chalazal end (often J-shaped), a mean size of 670 μm × 185 μm, and a length:width ratio of 3.6; (2) obovate to narrowly obovate seeds having an obtuse operculum with sunken hilum, a somewhat extended chalazal end, a mean size of 550 μm × 220 μm, and a length:width ratio of 2.5; and (3) elliptic seeds resembling the ordinary begonia seed type, having a nipple-shaped operculum, a mean size of 315 × 200 μm, and a length:width ratio of 1.6.

Most seed collections of B. cucullata var. cucullata belong to the first seed type, with the exception of collections Bartlett 21359 and Jorgensen 3473, which belong to the second and third types, respectively.

The seeds of B. cucullata var. arenosicolor (C. DC.) Smith & Schubert belong to the third seed type, with the exception of collection Fiebrig 5125, which belongs to the first seed type.

Testa cells adjacent to the collar are elongated in the first two seed types and are more polygonal in the third type. In spite of
the above-mentioned differences, all three seed types fully agree in their testal pattern, namely, undulated anticlinal walls and a granular to short linear cuticular structure.

Specimens Examined:
B. cucculata var. arenosicola, ARGENTINA: T.M. Pedersen 10232 (P). PARAGUAY: E. Hassler 6130 (P, isotype); E. Hassler 7884 (P, isotype); K. Fiebrig 5125 (L).
B. cucculata var. cucculata, BRAZIL: d’Alleizette s.n. (L); Irwin, Maxwell, & Wasshausen 19961 (P); Y. Mexia 5190 (U); Hj. Mosén 1598 (P). PARAGUAY: Jorgensen 3473 (US). URUGUAY: H.H. Bartlett 21359 (P).

Other Species Observed (Plate 19e–m).—The seeds of all the collections of the more widespread B. fischeri Schrank are narrowly ellipsoid with an obtuse micropylar end and with a sunk-en hilum and an extended chalazal end. They resemble the similar seed type of B. cucculata; however, they are somewhat longer, with a mean seed length of 795 μm. The anticlinal walls are mostly somewhat more strongly undulated, with pockets at their bases. The cuticular pattern is less prominent, and the outer walls sometimes reflect underlying pits. Begonia fischeri var. klugii Irmscher differs in its relatively longer micropylar end, being one-third of the seed length, whereas this is about one-fourth of the seed length in the other collections.

The seeds of B. alchemilloides Meisner ex A. DC., B. balansae C. DC., B. descoleana Smith & Schubert, B. meridensis A. DC., B. per-dusenii Brade, B. schmidtiana Regel, and B. subvillosa Klotzsch, mainly from Brazil and/or Paraguay and Argentina, resemble the elliptic seed type of B. cucculata in shape, undulated anticlinals, and in the granular to short linear cuticular pattern. The species vary somewhat in seed length, with a mean from 345 μm in B. subvillosa var. leptotricha (C. DC.) Smith & Wasshausen to 430 μm in B. descoleana. They also may show some differences in testal pattern, e.g., B. per-dusenii with broad anticlinals and B. alchemilloides with a less-pronounced cuticular pattern.

Specimens Examined:
B. alchemilloides, BRAZIL: H.S. Irwin c.s. 34478 (K).
B. balansae, PARAGUAY: B. Balansa 3281 (P).
B. descoleana, BRAZIL: G. Hatschbach 9944 (U).
B. fischeri var. fischeri, BRAZIL: G. Hatschbach 5338 (L); Prance & Silva 59701 (U). COSTA RICA: B. Hammel 8377 (MO). VENEZUELA: Steyermark & Rabé 96605 (P); Steyermark c.s. 100238 (P).
B. fischeri var. klugii, PERU: G. Klug 3389 (MO, cotype).
B. fischeri var. macroptera (Klotzsch) Irmscher, BRAZIL: B.B. Pickel 2466 (US).
B. fischeri var. palustris (Bentham) Irmscher, COLOMBIA: Hartweg 1022 (P).
B. meridensis, VENEZUELA: Holst & Liesner 3139 (MO).
B. per-dusenii, BRAZIL: L.B. Smith, Klein, & Schnorreberger 11728 (K).
B. schmidtiana, BRAZIL: B.K. Boom 15916, cult., Hort. Gent (L).
B. subvillosa var. leptotricha, PARAGUAY: K. Fiebrig 5354 (P, isotype).
B. subvillosa var. subvillosa, BRAZIL: G. Hatschbach 21525 (L); L.B. Smith & Reitz 1269 (US).

Ungrouped Species

Begonia organensis BRADE (Plate 18n).—Seed Structure and Micromorphology: The seeds of this species conform to the ordinary seed type and cannot be linked to either of the above-described groups. The mean seed size is 555 μm × 255 μm, with a length:width ratio of 2.2. The anticlinal walls are straight or slightly curved and sometimes are locally undulated. The distinct cuticular pattern consists of linear to undulated striae of varying length, continuous across the anticlinals.

Specimen Examined:
B. organensis, BRAZIL: D. Sucre c.s. 3005 (MO).

6.3. Section Knesebeckia (Klotzsch) A. DC.

PLATES 20, 21a–g

Section Knesebeckia was formerly considered a subsection of section Begoniastrum A. DC. by Warburg (1894). The section now includes the former subsection Rachia Klotzsch of the former section Magnisia Klotzsch (Irmscher, 1960) and the monotypic section Quadriperigonia Zieshenne, which was eliminated by the synonymy of the type species, B. abaculoides Zieshenne, with B. boissieri A. DC. (Smith and Wasshausen, 1983).

The species of this section are very diverse. Some show a close resemblance to species of Begonia, others are similar to species of Eupetalum, Ruizopavonia, and some other sections with bifid placentas. The section is characterized by anthers that are globose or obovoid and are much shorter than the filaments, which often are monodelphous. Some species are tuberous, and several also produce bulbs in the leaf axis. The section comprises about 67 Neotropical species, with a concentration in Mexico (Burt-Utley, 1985), and according to Barkley and Golding (1974), also includes about 10 Asian species.

The seeds of the species observed all conform to the ordinary begonia seed type; however, the section is not homogenous in seed structure and shows variation in micromorphological characters.

TYPE SPECIES.—Begonia incarnata Link & Otto (Plate 20a.d).

Seed Micromorphology: Anticlinal boundaries flat. Cuticular structure mainly short linear.

Specimen Examined:
B. incarnata var. incarnata, MEXICO: Liebmann 177 (US).
Other Species Observed (Plates 20b,c,e–n, 21a–g).—Seed structures vary between the Central American and the Mexican species.

Seed Structure and Micromorphology: Begonia xellemanii C. DC. and B. peltata Otto & Dietrich resemble B. incarnata in the thin, undulated anticlinal walls. The seeds of B. boissieri and B. ludwigi Irmscher resemble each other in the straight to curved anticlinal cell walls and in the short zigzag to granular cuticular ornamentation.

The seeds of B. gracilis H.B.K. and B. sandii Ziesenhenne strongly resemble those of some species of section Doratometra, especially B. wallichiana, in the relatively small seed size (mean seed length 300 μm in B. gracilis; 340 μm in B. sandii), straight or curved anticlinal walls, and the dense cuticular pattern, consisting of a mainly granular ornamentation. The seeds of B. angustiloba A. DC., B. falciloba Liebmann, B. ignea Warzewicz ex A. DC., and B. uniflora S. Watson resemble one another in thicker, straight or curved anticlinal walls and a mainly short zigzag cuticular ornamentation.

The seeds of the South American species studied deviate from the above-mentioned ones. The seeds of B. maynensis A. DC. and B. oellgaardii L.B. Smith & Wasshausen closely resemble one another in their short lengths, 280 and 295 μm, respectively, and a length:width ratio of 1.5. The seeds have broad anticlinals caused by thickening of the outer periclinal walls bordering the anticlinal walls. Anticlinal boundaries are locally sunken. The cuticular pattern is mainly granular to short undulated. The seeds of B. wollnyi Herzog resemble the above-described ones somewhat in their small size and in projecting anticlinals.

The seeds of the Brazilian species B. dichroa Sprague and B. olbia Kerchove resemble each other in size, with a mean length of 420 μm; thin, straight anticlinal walls; flat anticlinal boundaries; and the mainly granular to short linear cuticular ornamentation.

Specimens Examined:
B. angustiloba, MEXICO: M.L. Dignet s.n. (P).
B. boissieri, MEXICO: cult., van Veldhuizen 747 (WAG).
B. dichroa, BRAZIL: cult., Ziesenhenne s.n.
B. falciloba, MEXICO: M. Bourgeau 649 (P).
B. gracilis var. gracilis, MEXICO: Pringle 11452 (L).
B. xellemanii, GUATEMALA: cult., Ziesenhenne s.n.
B. ludwigi, ECUADOR: cult., Ziesenhenne s.n. CULTIVATED: van Veldhuizen 618 (WAG).
B. maynensis, BRAZIL: France c.s. 7409 (U).
B. oellgaardii, ECUADOR: M.A. Baker 6396 (US).
B. olbia, BRAZIL: cult., van Veldhuizen 434 (WAG).
B. sandii, MEXICO: cult., Ziesenhenne s.n.
B. uniflora, MEXICO: J. Roybal 647 (US).
B. wollnyi, BOLIVIA: cult., van Veldhuizen 435 (WAG).

6.4. Section Donaldia (Klotzsch) A. DC.
PLATE 21k–o

This section, comprising seven species, is characterized in part by pinnate leaves and by male flowers with two (sometimes four) tepals and ellipsoid anthers that are about as long as the filaments. No seeds were available for B. burlemarxii Brade or B. egleri Brade.

Type Species.—Begonia ulmifolia Willdenow was described in 1805. It has a wider distribution than other species in the section, being found in Venezuela, Guyana, and Trinidad, and it has been introduced and is naturalized in Sri Lanka (Jayasuriya, 1983).

Seed Structure: Seeds ellipsoid, mean size 290 μm × 190 μm, length:width ratio 1:5. Testa cells polygonal, with curved anticlinal walls. Sample from Sri Lanka differs by more slender seeds with thinner, straight anticlinal walls. Seeds resembling those of B. gracilis (section Knesebeckia).

Seed Micromorphology: Cuticular pattern consisting of short linear to almost granular and short zigzag striae.

Specimens Examined:

Other Species Observed.—Two of the other species observed are limited to Bolivia, and two are limited to Brazil (see “Specimens Examined,” below).

Seed Structure and Micromorphology: The seeds of the other four species studied also are relatively small, not exceeding 400 μm, and conform to the ordinary begonia seed type. They differ in anticlinal walls, from straight in B. dasycarpa A. DC. to undulated in B. chaetocarpa Kuntze var. chaetocarpa. They resemble the seeds of B. ulmifolia in cuticular pattern except for B. dasycarpa, which has long zigzag striae.

Specimens Examined:
B. bangii Kuntze, BOLIVIA: A. Miguel Bang 406 (K).
B. chaetocarpa var. chaetocarpa, BOLIVIA: O. Kuntze s.n. (B, isotype).
B. chaetocarpa var. glabriflora Smith & Schubert, BOLIVIA: H.H. Rusby 690 (US, isotype).
B. dasycarpa, BRAZIL: A. Glaziou 15388 (P).
B. jaairii Brade, BRAZIL: G. Pedro do Cavalo 752 (US).

Discussion

SEED MORPHOLOGY

The seeds of about 235 Neotropical Begonia species, representing 39 sections, were studied using SEM. No seeds were available for study in the monotypic sections Cylindrobegonia, Parietoplacentaria, Plurilobaria, and the dubious monotypic section Dasystyles.

Almost all seeds studied show differentiation between collar and other testa cells, characteristic for Begonia. The only exceptions are found in species B. antioquensis and B. hexandra.
of section *Casparya*, the seeds of which show neither a distinct collar nor a borderline with the operculum.

As is the case in African and Asiatic begonias, the seeds of the Neotropical species exhibit an appreciable diversity in seed size and structure. This diversity is not as wide as in the African begonias (de Lange and Bouman, 1992), in which all sections are distinguishable from one another on the basis of seed characters.

The seeds of Neotropical begonias vary in shape from almost globular to narrowly ellipsoidal. The lowest length/width ratio (1.2) is found in *B. hexandra*; the highest one (8.1) is found in *B. fruticosa* (section *Trendelenburgia*). Seed shape may be determined by flattened, extended, or swollen chalazal ends. A flat chalazal end is caused by contact with the ovary or fruit wall. Most seeds have a mean length between 300 μm and 600 μm; the shortest, with a mean length of 225 μm, are found in *B. corredorana* (section *Ruizipavoniana*), and the longest ones, with a mean length of 1450 μm, are found in a collection of *B. fruticosa*.

The mean number of collar cells in the seed circumference is mostly between 10 and 12; however, this may be as low as eight in a collection of *B. glabra* (section *Enita*) and as high as 23 in a collection of *B. pectennervia* (section *Casparya*). The collar cells are mostly distinctly elongated; their mean length varies from 100 μm in *B. wallichiana* (section *Doratometra*), to 290 μm in *B. maculata* (section *Gaertdia*), and to 325 μm in *B. fruticosa*. The mean collar-cell length:seed length varies from 1.9 in *B. maculata* to 5.7 in *B. urticae* (section *Casparya*). The other testa cells are mostly polygonal, sometimes elongated near collar cells. Their anticlinal walls are straight (as in sections *Pritzelia* or *Ewaldia*) or are curved or undulated (as in sections *Casparya* or *Hydristyles*). The anticlinal boundaries are mostly flat but are sometimes sunken or locally sunken (as in section *Warburgina*).

The cuticular ornamentation varies greatly in pattern, thickness, and roughness. The cuticular pattern may be granular, linear, undulated, or zigzag. The surface of the cuticle may be smooth (section *Urniiformia*), faint, pronounced, or even forming a net-like structure of pleats (section *Trachelocarpus*). The roughness varies from fine and dense (section *Lattistigma*) to rough, as in many species of section *Casparya*. Sometimes the structure of the underlying periclinal wall is reflected, showing pits or pockets at the bases of undulated anticlinal walls. A cuticle with a double structure, i.e., with more elevated, scattered foldings next to a regular cuticular pattern, is especially found in section *Casparya*.

**DELIIMINATION AND INTERRELATIONSHIPS OF NEOTROPICAL SECTIONS**

Within the Neotropical begonias, a number of sections show a special seed structure characteristic at the sectional level. All these sections have a relatively restricted geographical distribution; one or more of such sections are found in each of the three main areas in which Neotropical begonias are found. The sections with a specialized seed structure have a limited number of species, with the exception of sections *Casparya* and *Gobenia*.

Of the Brazilian or mainly Brazilian sections, the following five sections have a characteristic seed structure.

In section *Trachelocarpus* the seeds are relatively large, with a rather unique cuticular structure consisting of upright or folded-over pleats. The seeds of section *Solanamnthera* are long because of their extended chalazal end. The long seeds in section *Trendelenburgia* have both extended micropylar and chalazal ends. In section *Enita* (*Wageneria*) the micropylar and/or chalazal cells of the seeds are uncollapsed and air-filled, resembling balloons. In section *Scheidweileria* the surface of the flattened chalaza is pronounced because of deep, collapsed testa cells and an often broadly nipple-shaped operculum.

The other Brazilian or mainly Brazilian sections do not have a characteristic seed structure at the sectional level, and most of their species have seeds that conform to the ordinary begonia seed type. In some cases one or more species within a section may deviate from this ordinary type.

The possible relationship between sections *Ewaldia* and *Scheidweileria*, as suggested by the successive numbering of the two sections in *Die natürlichen Pflanzenfamilien* (Warburg, 1894; Irmscher, 1925), is supported by seed structure. The seeds of the type species *B. lobata* of section *Ewaldia* resemble those of section *Scheidweileria*.

The section *Pritzelia* is quite diverse in seed morphology. Within the section, a number of species observed deviate by having a more pronounced and coarse zigzag cuticular striae.

Seed structure does not provide arguments for a separate section *Bradea* as proposed by Toledo (1946). The seeds of the type species *B. rufosericea* closely resemble those of *B. arborescens* of section *Steineria*.

The seeds of species of section *Lattistigma* conform to the ordinary begonia seed type and resemble the seeds of some species of section *Gireoudia*, e.g., *B. cardiocarpa*.

Of the sections mainly confined to the Andean and Guianan regions, five have characteristic seeds. In section *Casparya* the seeds are recognizable by a combination of characters, especially the roughness of the testal surface, the mostly undulated anticlinals, the flat operculum, and sometimes the double structure of the cuticle. On the basis of a combination of these characters, several species groups can be discerned, but they do not match the subsectional classification of Irmscher (1925). Unfortunately, we cannot contribute to the discussion on the status of the former sections *Begoniella* and *Semibegoniella* because no seeds of these taxa could be examined.

Section *Rossmannia* is the only Andean section having narrowly elliptic seeds with a swollen micropylar and an extended chalazal end. The seeds of *B. rossmannianae* resemble those of the *B. cucullata—B. fischeri* group (section *Begonia*) in shape and size, but they differ in the presence of straight anticlinal walls.
Seed structure in section *Hydristyles* is quite diverse. Seed micromorphology provides arguments for the inclusion of section *Warburgina* in section *Hydristyles*. The seeds of *B. comata* resemble seeds of species of section *Hydristyles*, like *B. andina* and *B. unduaeensis*, in their elongated testa cells with strongly undulated walls.

The seeds of section *Gobenia* are characterized by an irregular seed shape, a broadly nipple-shaped operculum, and an often flattened chalazal end with more elevated anticalinal walls. The seeds of section *Gobenia* resemble those of section *Scheidweileria*. Seed micromorphology supports the opinion of Smith and Wasshausen (1986) that *B. sodiroi* belongs to section *Gobenia*. The synonymy of *B. sodiroi* with *B. oaxacana* (section *Hexapera*) as stated by Barkley and Golding (1974) is not supported.

The other mainly Andean sections all have seeds that conform to the ordinary seed type and only differ in details. Seed micromorphology does not contradict a relationship between sections *Lepisia* and *Tittelbachia* and supports the inclusion of section *Huszia* in section *Eupetalum*, as proposed by Smith and Wasshausen (1979, 1986). The seeds of the section type, *B. geraniiformia*, resemble those of a number of species of the former section *Huszia*. The placement of *B. micranthera* in section *Australes* (Smith and Schubert, 1941) also is supported by seed morphology.

*Begonia exalata*, of the monotypic section *Apteron*, differs in fruit structure and growth form, but the general morphological characters as well as the seed structure indicate a relationship with section *Eupetalum*. *Begonia trujillensis* was initially placed in section *Apteron* by its author on the basis of the regularly two-parted styles (Smith, 1973; Barkley and Golding, 1974). Seed micromorphology clearly shows that this species belongs to section *Casparya*.

The seeds of the type species of section *Barya*, *B. monadelpha*, and to a lesser extent the seeds of *B. soror*, agree with those of section *Gobenia* in their somewhat irregular shape and the broadly nipple-shaped opercula.

The elimination of the monotypic Colombian section *Saueria* by synonymy of its type species, *B. sulcata*, with a species of section *Pritzelia*, is supported by seed morphology.

Of the sections mainly confined to the Central American and Caribbean regions and Mexico, only the seeds of the monotypic section *Urniforma* show special characters. *Begonia heydei* is the only Neotropical species having seeds with a smooth cuticle.

The seeds of the large section *Gireoudia* all conform to the ordinary begonia seed type and do not show a distinct grouping of the seeds. The inclusion of section *Auriformia* is not disproved by seed micromorphology. The seeds of the former type species *B. bakeri* (= *B. cardiocarpa*) resemble those of other collections of *B. cardiocarpa* and of *B. involucrata*. Seed morphology does not provide arguments for or against a separate section *Dissepigobenia*. The section most probably should be included in section *Knesebeckia*, as the kind of placentation also is found in some species of this section (Doorenbos et al., 1998).

The seeds of the other three sections all have relatively small seeds and do not show special characters.

The majority of the seeds of all seven sections not restricted to one of the main geographical areas conform to the ordinary seed type. Seed micromorphology generally only provides restricted arguments for delimitation of sections or relationships between these sections. The sections *Ruizopavonia*, *Doratometra*, and *Begonia* are mutually difficult to delimit (Irmscher, 1949). All three sections are rather heterogenous in seed structure and have species or a group of species with a deviating seed structure. The transfer of *B. filipes*, *B. humilis*, and *B. hirtella* from section *Begonia* to section *Doratometra* as referred to by Barkley and Golding (1974) is supported by seed micromorphology. The conspecificity of *B. filipes* and *B. hirsuta* as suggested by Burt-Utley (1984) is not supported by seed micromorphology. The seeds of *B. prieurii* and *B. steysmarkii* of section *Doratometra* deviate from the seeds of the other species of this section by the presence of knobbles on the outer anticlinal walls and by thicker, distinctly undulated anticalinal walls. The seeds of *B. steysmarkii* resemble those of some species in section *Casparya*.

The seeds of the species of section *Ruizopavonia* are rather heterogenous. The seeds of a number of species, for example, *B. bracteosa* and *B. suprafastigiata*, resemble those of some species of section *Begonia*. The scrobiform seeds of *B. cuatrecasiana* resemble those of section *Rossmannia*, and seeds of *B. estrellensis* resemble those of section *Hydristyles*. Seed micromorphology does not support the synonymy of *B. udissilvestris* with *B. carpinoefolia* (Barkley and Golding, 1974). *Begonia udissilvestris* most probably does not belong to section *Ruizopavonia*. Doorenbos et al. (1998) placed *B. oaxacana* of the monotypic section *Hexapera* together with *B. udissilvestris* in section *Parietoplaentalia*. This opinion is supported by the resemblance of the seeds of *B. udissilvestris* to those of *B. oaxacana*.

Seed micromorphology could not provide arguments for or against the inclusion of *B. thiemei* and *B. correodora* in section *Gireoudia* as indicated by Burt-Utley (1985).

Within section *Begonia*, the *B. cucullata—B. fischeri* group is characterized by a testal pattern of undulated anticalinal walls, a granula to short linear cuticular structure, and, partly, a narrowly ellipsoid or obovate seed shape.

The inclusion of section *Cyathocnemis* in section *Begonia* is supported by seed structure.

**POSSIBLE INTERCONTINENTAL RELATIONSHIPS**

Our knowledge of the intercontinental relationships of begonias is rather meager. The great majority of *Begonia* sections have a distribution that is restricted to one continent. Warburg (1894) classified all *Begonia* species into African, Asian, and American sections; however, Irmscher (1925) was of the opin-
ion that section Begoniastrum was intercontinental, comprising species of American and Asian origin. Baranov and Barkley (1972) changed the name of section Begoniastrum to Begonia, in accordance with the ICBN, and split off a separate section Knesebeckia. According to Barkley and Golding (1974), sections Begonia and Knesebeckia comprise about 12 and about 10 Asian species, respectively. Serious doubts, however, exist about the validity of the delimitation of these sections. Doorenbos et al. (1998) moved the Asian species of both section Begonia and section Knesebeckia to section Diplolclinium.

As shown in this study, the seeds of the American representatives of section Knesebeckia are quite diverse in structure. Seeds of the Asian section Diplolclinium observed by us also conform to the ordinary Begonia type: they are mostly relatively small and show some variation in anticlinal walls and cuticular structure. Seeds of the Asian Knesebeckia species also show appreciable variation in seed morphology and do not closely resemble the American species of section Knesebeckia or those of section Diplolclinium. Of the Asian species of section Begonia, only B. labordei Léveillé could be studied by us. The seeds of this species conform to the ordinary begonia seed type and do not show any specific character that points to or against a relation with the American species.

A. De Candolle included in his section Casparya a number of Indo-Malaysian species, such as B. multangula Blume, B. robusta Blume, and B. siltetensis (A. D.) C. B. Clarke, now belonging to the Asian section Sphenanthera A. DC. The seeds of species in section Sphenanthera are relatively small and have a mainly granular structure. The seeds of the above-mentioned species fit well with those of section Sphenanthera. There are no arguments for a direct relationship of section Casparya with Asian species.

As far as we know, no suggestions have been made about intercontinental relationships between Neotropical and African begonias.

**SEED STRUCTURE IN RELATION TO DISPERAL AND GROWTH FORM**

Field observations on the dispersal of Begonia seeds are rare. The great majority of the Neotropical Begonia species seems to be wind dispersed (anemochory; see van der Pijl, 1972). Seed dispersal is mostly anemoballistic, i.e., the winged fruit is shaken by wind and the seeds are gradually released through pores or slits. This means of dispersal holds for the majority of the Neotropical sections, including large sections, such as Begonia, Gireoudia, Knesebeckia, and Pritzelia, which generally grow in a more open and often dry vegetation. Capsular motion may be promoted by elongated fructescences exposed above the leaves, enlargement of the median wing into a vane, or by persistent bracteoles. The seeds of these species are medium-sized and conform to the ordinary seed type.

Special adaptations to wind dispersal are the increase of the surface to volume ratio as seen in narrowly ellipsoid fusiform seeds, the decrease of specific gravity (mass) caused by uncollapsed, air-filled testa cells, as in balloon seeds, and promotion of laminar air flow by surface roughness. These adaptations also may occur in varying combinations. Adaptations in seed shape in combination with inflated cells are known in sections Rossmannia, Solanthera, and Trendelenburgia and in the B. cucullata—B. fischeri group of section Begonia. Typical balloon seeds also are found in section Enita, whereas a more pronounced surface caused by more raised anticlinal walls is seen in seeds of sections Scheidweileria and Gobenia. Wind dispersal, however, seems neither likely nor effective in species from humid and/or closed-forest vegetation.

On the basis of fruit and seed morphology, it is rather speculative to suggest other types of dispersal in Neotropical begonias. Secondary seed dispersal by rain-wash may occur in the majority of the begonias, including the wind dispersed ones. Rain-wash is supposed to be the most important means of dispersal for most species of the African sections Filicibegonia, Loasibegonia, and Scutobegonia, growing in the sheltered environment of the tropical rain forest where wind is an ineffective vector in dispersal. Their fruits do not open but rot away. Seeds of species in these sections are small and are often provided with a thick, pronounced, cuticular ornamentation (de Lange and Bouman, 1992). Such a combination of fruit and seed characters is not found among the Neotropical begonias.

A number of Neotropical Begonia sections have fruits and seeds that are not adapted to wind dispersal. The species of the epiphytic section Trachelocarpus are characterized by solitary, subsessile fruits with narrow wings somewhat hidden underneath the leaves, as expressed by the name B. rhizocarpa (= B. depauperata), and large seeds with a very pronounced cuticular pattern. The means of seed dispersal is unknown. A combination of accidental dispersal by rain and by adhering to animals (epizoochory) seems to be the most probable way of dispersal

The species of section Casparya act as rattleburs; their fruits have horns instead of wings, and the seeds are provided with striking cuticular patterns, such as prominent, sometimes pliicate foldings or a double structure that might function in dispersal by rain wash. Seeds seem to be dispersed in different ways. Passing animals may catch the horns and shake the fruits, scattering seeds (zooballistics), or seeds may adhere to animals.

None of the Neotropical begonias have fruits adapted to rain ballistics as in the Asian section Platycenrum, where the two shorter wings form a cup to catch raindrops. Moreover, none of the Neotropical begonias have fruits or seeds that seem adapted to frugivores or to ant dispersal. Animal-dispersed begonias with fleshy, often colored fruits are known in a number of African sections. These sections show trends toward bigger seeds, loss of cuticular ornamentation, and a thick exotesta, and they may have aril-like appendages (de Lange and Bouman, 1992).

In the Neotropics, seeds without cuticular ornamentation are known only from B. heydei (section Urmiformia). This species, from the wet montane zone of Central America, deviates from
all other begonias by a one-celled ovary with three long, hollow, fleshy horns. Fruit dehiscence and seed release have not been described in detail.

The wingless fruits of *B. exalata* (section *Apteron*) suggest another means of dispersal; however, the seeds are of the ordinary begonia type, and seed micromorphology does not provide an indication for dispersal.

The means of seed dispersal often seems to be related to habitat and growth form (Burt-Utley, 1985). Begonias with special adaptations to wind dispersal are mostly climbers and/or epiphytes or have a tendency to do so. For example, this holds in sections *Enita*, *Rossmannia*, *Solananthera*, *Trendelenburgia*, and in species of section *Gobenia*. The rattleburrs of section *Casparya* grow in the wet montane forest, where wind is less effective.

Seed dispersal of the Neotropical begonias, and most probably that of the Asian ones, distinctly differs from seed dispersal in African begonias. In the Neotropical begonias wind dispersal is predominant, and alternative types of dispersal are restricted to a limited number of sections. In Africa only about one-fifth of the *Begonia* species are wind dispersed, almost two-fifths are animal-dispersed, and over two-fifths are dispersed by a combination of rain-wash and epizoochory (de Lange and Bouman, 1992).
PLATE 1.—Seeds of sections Trachelocarpus and Solanthera: a. B. herbacea (Lisodococeales s.n.), x125; b. B. herbacea var. ellipticifolia (Ule 4240), x110; c. detail testa, x500; d. B. olbia (van Veldhuizen 434), detail testa, x610, g. seed, x140; e. B. wollnyi (van Veldhuizen 435), x240; f. B. dichroa (Ziesenhenne s.n.), x140; h. B. ulmifolia (Hekking 1428), x210, k. detail chalaza, x420; j. B. dasycarpa (Glaziou 15388), detail testa, x760, l. seed, x160; m. B. chaetocarpa var. chaetocarpa (Kuntze s.n.), x210; n. B. chaetocarpa var. glabraflora (Rusby 690), x180; o. B. bangii (Bang 406), x180.
REQUIREMENTS FOR SMITHSONIAN SERIES PUBLICATION

Manuscripts intended for series publication receive substantive review (conducted by their originating Smithsonian museums or offices) and are submitted to the Smithsonian Institution Press with Form SI-36, which must show the approval of the appropriate authority designated by the sponsoring organizational unit. Requests for special treatment—use of color, foldouts, case-bound covers, etc.—require, on the same form, the added approval of the sponsoring authority.

Review of manuscripts and art by the Press for requirements of series format and style, completeness and clarity of copy, and arrangement of all material, as outlined below, will govern, within the judgment of the Press, acceptance or rejection of manuscripts and art.

Copy must be prepared on typewriter or word processor, double-spaced, on one side of standard white bond paper (not erasable), with 1 1/4” margins, submitted as ribbon copy (not carbon or xerox), in loose sheets (not stapled or bound), and accompanied by original art. Minimum acceptable length is 30 pages.

Front matter (preceding the text) should include: title page with only title and author and no other information; abstract page with author, title, series, etc., following the established format; table of contents with indents reflecting the hierarchy of heads in the paper; also, foreword and/or preface, if appropriate.

First page of text should carry the title and author at the top of the page; second page should have only the author’s name and professional mailing address, to be used as an unnumbered footnote on the first page of printed text.

Center heads of whatever level should be typed with initial caps of major words, with extra space above and below the head, but no other preparation (such as all caps or underline, except for the underline necessary for generic and specific epithets). Run-in paragraph heads should use period/dashes or colons as necessary.

Tabulations within text (lists of data, often in parallel columns) can be typed on the text page where they occur, but they should not contain rules or numbered table captions.

Formal tables (numbered, with captions, boxheads, stubs, rules) should be submitted as carefully typed, double-spaced copy separate from the text; they will be typeset unless otherwise requested. If camera-copy use is anticipated, do not draw rules on manuscript copy.

Taxonomic keys in natural history papers should use the aligned-couplet form for zoology and may use the multi-level indent form for botany. If cross referencing is required between key and text, do not include page references within the key, but number the keyed-out taxa, using the same numbers with their corresponding heads in the text.

Synonymy in zoology must use the short form (taxon, author, year/page), with full reference at the end of the paper under “Literature Cited.” For botany, the long form (taxon, author, abbreviated journal or book title, volume, page, year, with no reference in “Literature Cited”) is optional.

Text-reference system (author, year/page used within the text, with full citation in “Literature Cited” at the end of the text) must be used in place of bibliographic footnotes in all Contributions Series and is strongly recommended in the Studies Series. “Jones, 1910:122” or “Jones (1910:122),” If bibliographic footnotes are required, use the short form (author, brief title, page) with the full citation in the bibliography.

Footnotes, when few in number, whether annotative or bibliographic, should be typed on separate sheets and inserted immediately after text pages on which the references occur. Extensive notes must be gathered together and placed at the end of the text in a notes section.

Bibliography, depending upon use, is termed “Literature Cited,” “References,” or “Bibliography.” Spell out titles of books, articles, journals, and monograph series. For book and article titles use sentence-style capitalization according to the rules of the language employed (exception; capitalize all major words in English). For journal and series titles, capitalize the initial word and all subsequent words except articles, conjunctions, and prepositions. Transliterate languages that use a non-Roman alphabet according to the Library of Congress system. Underline (for italics) titles of journals and series and titles of books that are not part of a series. Use the parentheses/colon system for volume (number):pagination; “10(2):5-9.” For alignment and arrangement of elements, follow the format of recent publications in the series for which the manuscript is intended. Guidelines for preparing bibliography may be secured from Series Section, SI Press.

Legends for illustrations must be submitted at the end of the manuscript, with as many legends typed, double-spaced, to a page as convenient. Illustrations must be submitted as original art (not copies) accompanying, but separate from, the manuscript. Guidelines for preparing art may be secured from the Series Section, SI Press. All types of illustrations (photographs, line drawings, maps, etc.) may be intermixed throughout the printed text. They should be termed Figures and should be numbered consecutively as they will appear in the monograph. If several illustrations are treated as components of a single composite figure, they should be designated by lowercase italic letters on the illustration; also, in the legend and in text references the italic letters (underlined in copy) should be used: “Figure 9b.” Illustrations that are intended to follow the printed text may be termed Plates, and any components should be similarly lettered and referenced: “Plate 9b.” Keys to any symbols within an illustration should appear on the art rather than in the legend.

Some points of style: Do not use periods after such abbreviations as “mm, ft, USNM, NNE.” Spell out numbers “one” through “nine” in expository text, but use digits in all other cases if possible. Use of the metric system of measurement is preferable; where use of the English system is unavoidable, supply metric equivalents in parentheses. Use the decimal system for precise measurements and relationships, common fractions for approximations. Use day/month/year sequence for dates: “9 April 1976.” For months in tabular listings or data sections, use three-letter abbreviations with no periods: “Jan, Mar, Jun,” etc. Omit space between initials of a personal name: “J.B. Jones.”

Arrange and paginate sequentially every sheet of manuscript in the following order: (1) title page, (2) abstract, (3) contents, (4) foreword and/or preface, (5) text, (6) appendices, (7) notes section, (8) glossary, (9) bibliography, (10) legends, (11) tables. Index copy may be submitted at page proof stage, but plans for an index should be indicated when the manuscript is submitted.
